The occurrence of this *mal de misère*, the "Mailändische Rose" of the Germans, though known in Central Italy, has never become so prevalent there as in the northern portion of the kingdom. In the province of Rome its very existence has been unknown to people in general until the publication of the recent report of Dr. Zampa, the medical officer of health for the province, from which it appears that when the sanitary inspection was made in 1899 some 150 cases were discovered distributed throughout the district, but occurring chiefly at Onano, Piglio, Proceno, Palestrina, Cave, and Valmontone. More than one-half of these (80 cases) were found at Onano, where indeed the disease has assumed an endemo-epidemic character. The date of its first appearance in the province is uncertain, but in 1869 it was known to have already existed for some time. In 1881 there were only about 30 "pellagrosi," but in 1897 the number had risen to over 100, located principally at Onano and Piglio. No connexion has been traced between the disease and topographical conditions, the affected communes lying indifferently sometimes in the malarial, sometimes in the non-malarial, zone. The malady attacks by preference the agricultural classes, but in the rural communes does not altogether spare artisans, even those better off, the explanation being partly that less difference exists here than elsewhere in the conditions under which the agricultural and artisan classes respectively live, partly because of the widespread misery caused by the deficiency or absence of crops in some localities during the last two or three years owing to which their means of subsistence were reduced to maize alone. Onano, where the disease is most prevalent, lies amongst the hills at an elevation of close upon 1800 feet above sea-level, in a situation naturally salubrious, but its houses are so constructed for the most part as to be nothing better than damp grottoes, dirty and dark, with no ventilation whatever. The drinking-water is very scarce and after rain it is often muddy, and the only food for the poor people during the greater part of the year is "polenta," a kind of porridge made of maize meal seasoned with a little salt. The remedies proposed by Dr. Zampa consist in limiting the consumption and improving the supply of maize by exercising care in selecting and storing the grain, so that the people may get it sound, dry, and of good quality; at the same time ameliorating the insanitary conditions of the houses and their surroundings which conduce to the production of the disease; and, finally, by the appointment of a provincial commission with communal committees, such as exist in other districts where the disease is of old standing, for the purpose of collecting information as to its spread, of advising or adopting measures for its prevention, and of organising the distribution of subscriptions from public or private sources amongst its victims.

Hæmorrhagic Small-pox near Salerno.

Seven cases of "black" small-pox, one of which has already proved fatal, are reported from Nocera Inferiore on the Naples and Salerno line of railway. Much apprehension is felt lest the disease should spread and precautionary measures have been taken by the prefect in regard to the isolation of those attacked and the vaccination of the population of Nocera and its neighbourhood.

The Ostia Experiment.

The period assigned to the experiment in the Roman Campagna planned by Dr. Patrick Manson is now so near its close that the successful result of this also may be regarded as assured. Dr. Sambon and Dr. Low, as well as the artist Signor Terzi and the two servants who have passed the last three months with them in this highly malarious part of Italy, have not only succeeded in escaping infection thanks to the protection afforded them by their mosquito-proof house, but by [illegible] strong testimony to [illegible] air of Ostia. After [illegible] of a pestiferous swamp through the hottest and most unhealthy time they are now leaving the dreaded Campagna looking as "fit" and bronzed as if their summer had been spent in the Swiss Alps or the Scottish Highlands. In sad contrast to this pleasing picture is the condition of the inmates of the nearest peasant's house little more than 100 yards distant [illegible] teristic [illegible] ad the spleen greatly enlarged. A [illegible] of their dwelling sufficed to reveal [illegible] for in the cobwebs on the walls, [illegible] y dark corner of the house, lurked numerous specimens of the fe[illegible] a contrast as is here presented [illegible] lection, that the evil repute of [illegible] as pestilential depends upon no real insalubrity of the place itself, inherent in its soil or in its air, but upon fortuitous, non-essential, and perhaps easily removeable, conditions. Besides attaining the immediate object of the expedition, [illegible] obser- [illegible] upon [illegible] sition which they assume when at rest, their mode of flying, and their respective prevalence in the different months. The full report of the expedition, to the attractiveness of which the beautiful drawings by Signor Terzi will greatly add, is looked forward to with much interest.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Accident to Professor Rieder.

A GOOD while ago the Government of Turkey, having resolved to put medical education in that country on a better footing, requested the German Government to select a competent teacher who would be able also to organise a satisfactory system of medical education in Turkey. Dr. Rieder, extraordinary professor of surgery in the University of Bonn, was chosen for the new appointment and came to Constantinople two years ago. He proved himself admirably fitted for the post and the manner in which he performed the work intrusted to him has been beyond all praise. He taught in a newly-constructed hospital at Gulhaneh in a corner of the place where the Byzantine Imperial palaces used to be; the beds are 200 in number, 40 of them being for women. He succeeded in introducing two innovations to which the social conditions prevailing in Turkey presented serious obstacles and which had baffled all previous efforts in the same direction, for he brought about the withdrawal of distinctions between patients belonging to different races and religious beliefs and he obtained the permission, so necessary to medical education, to perform necropsies on all patients dying in the above hospital. In addition to his duties as a teacher Professor Rieder was extraordinary surgeon to the Imperial palace and had general control of the building operations going on at the new medical school which is in course of erection at Haidar-Pasha near the English cemetery. The original estimate of the cost of this building was £T200,000, but Professor Rieder made such modifications in the plans as raised the estimate to £T600,000. The building is now roofed in, and he used to visit it three times a week. On Oct. 2nd, while on the third storey, the part on which he was standing gave way and he fell to the ground from a height of 49 feet, sustaining fractures of both legs and thighs, some ribs, and the dorsal spine, followed by paralysis of the lower limbs, rectum, and bladder. When the sad news became known all who were acquainted with Professor Rieder were painfully affected. Dr. Hambouroglou of the German Hospital, together with the surgeon of the German despatch vessel *Loreley*, were promptly in attendance. Dr. Zick of Hamburg and Professor Schede of the University of Bonn were telegraphed for, and Dr. Zick has already arrived. Professor Rieder has been removed from Haidar-Pasha to the Gulhaneh Hospital, where he is now lying.

The Shah of Persia.

When in Constantinople the Shah presented £T500 to the Persian Hospital there.

Archæology in the Island of Cos.

Two years ago Dr. Rudolf Herzog of Tübingen undertook excavations in the island of Cos with the view of finding the temple of Æsculapius. At a depth of 80 centimetres [illegible] bring which represented [illegible] At a depth of two [illegible]) in the neighbourhood [illegible] l two columns and not far from them the remains of an aqueduct and a small statue of a young man. Great importance is attached to Dr. Herzog's discovery of the supposed temple of Æsculapius. The excavations are still in progress and it is hoped that many antiquities will be found.

Oct. 11th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Census in the United States.

ALTHOUGH the exact population of the United States has not yet been made public, yet sufficient has been published to make a reasonable conjecture as to an approximate estimate. It is likely that the total number of inhabitants of the United States will be found not to reach 80,000,000. The improvement in the sanitary conditions of large towns, [illegible] this point says: "It is perhaps true that there are now some localities of considerable extent in the United States where, if it were not for the [illegible] tion, and also that there is [illegible] among the immigrants, the [illegible] means hold its own on accoun[illegible] the native American element [illegible] facts that the new census [illegible] light upon interesting questions touching the present tendencies of population in the United States. If the statistics are to be relied upon the increase in population which was due to the excess of births over deaths was about 14 per cent. for the 10 years 1880–90; but, further, assuming the correctness of the immigration statistics for the past decade, if we accept the estimates which call for a population of 80,000,000 this year, we shall have to look to an excess of births over deaths for a gain of almost 22 per cent. To anyone familiar with vital statistics it is evident without further discussion that such a radical change in the conditions of population increase in the United States could not possibly have taken place. Even if one were to be content with estimating that we should have gained population at the same rate in the current decade as in the one preceding it would still be necessary on account of the falling off in immigration to rely upon a considerably higher rate of gain in the excess of births over deaths in order to bring up the total and there is not sufficient reason to believe that the actual census work will show any such gain. There is no doubt whatever that the birth-rate among native-born Americans has been decreasing not only steadily but even with some rapidity. The native-born population of the United States resemble in this respect the people of Great Britain and to a lesser extent those of France, in which countries although improved sanitary conditions and methods of treating disease are diminishing the death-rate, yet at the same time, and especially in the latter country, there has been a great falling-off in the birth-rate. Of course, when Great Britain is referred to, it is understood that the falling-off in the birth-rate has as yet been inconsiderable, but that there is a tendency in that direction cannot be denied.

Yellow Fever in Cuba.

This disease has been prevalent to a somewhat alarming extent in Havana for the past two months, and especially among American residents. At the present time, although perhaps the epidemic shows signs of waning, yet the situation is still sufficiently alarming. The reports of the United States Marine Hospital Service show that there were 73 deaths from yellow fever in the week ending Sept. 1st, more than double the number of deaths from the same cause in the preceding week. During the month of September 267 cases were officially reported, with a mortality of 25 per cent.; 84 cases, according to the latest accounts, are under treatment, and 25 fresh cases have been reported within the last 48 hours. It is also rumoured that many cases are not reported as yellow fever at all, because of the non-development of albumin symptoms, although all the other symptoms are unmistakeable. The physicians are unwilling to diagnose as yellow fever the non-albuminous cases in order not to swell the yellow fever statistics. However, this statement is not authenticated. While the infection is well scattered over the entire city, the larger number of cases have occurred on the Prado and in sections of the city occupied by the wealthier classes. During the month of August work on the Havana electric car line has been under way, and extensive excavation and street grading have been performed. Whether the work necessitating the tearing up of the streets along the street car line at this time of the year is altogether reponsible for the increased amount of sickness in Havana is hard to determine. It is certain that neither yellow fever nor malaria is confined to those parts of the city in which the work is being done, and yet there has been considerable sickness among labourers, most of them Spanish and American, engaged in the construction of the car line. In the public health reports of the Marine Hospital Service for Sept. 21st is included the following extract from *La Habana Medicina*, an influential scientific review published in Havana: "The gravity of the present epidemic of yellow fever is truly alarming. A greater number of invasions probably occurred in 1895, but the general character of the disease was rather benign. In the present year, on the contrary, it assumes the utmost gravity, the mortality exceeding 30 per cent. The following are the data from the principal sanitariums of Havana for the eight months from Jan. 1st to August 21st: Quinta de Dependientes 136 cases, with 38 deaths, the percentage of mortality being 27·94; Quinta la Covadonga, 51 cases, with 20 deaths, the percentage of mortality being 39 91; Quinta del Centro Gallego, 38 cases, with 12 deaths, the percentage of mortality being 31 57; and Quinta del Rey, four cases, with three deaths, the percentage of mortality being 75. Analysing these figures, those of the Quinta de Dependientes attract the most attention; more patients have been treated there than in the other three sanitariums put together, with the fortunate result that the relative mortality has been less than in any other. As we see, yellow fever still dominates our local pathology, while other diseases sensibly diminish and with them the general mortality. It does not suffice to combat this infection with the greatest hygiene. As the principal factor against it a therapeutic agent of sure action is needed and unfortunately we do not posses it. Sero-therapy is the only source to furnish it." While possibly right in saying that a serum may be discovered which will act as an efficient antidote against yellow fever, *La Habana Medicina* is wrong in asserting that the disease cannot be controlled and even entirely extirpated by good sanitation and by methods of hygiene generally. This fact has been proved in so many instances that it is unnecessary to touch upon it further. Nothing but a thorough new sewage system which might cost any sum from £2,000,000 to £3,000 000 will effectually solve the problem of cleansing Havana and of abolishing yellow fever. If the late Colonel Waring's plans had been carried out in their entirety Havana would probably by this time be in a fairly healthy condition. It must be understood that the money for these radical remedial measures will have to be mainly forthcoming from Americans, as the Cubans themselves, being immune, care not whether the city is filthy or clean. In some of the American lay journals there is a tendency to reflect unfavourably on General Wood, but undoubtedly he has done his best with the means at his disposal.

Oct. 6th.

Obituary.

LEWIS ALBERT SAYRE, M.D., LL.D.

ONE of the best-known American surgeons, Dr. Lewis Albert Sayre, passed away at his home in New York on Sept. 21st at the ripe age of 80 years. He was born on Feb. 29th, 1820, and he graduated in medicine in 1842. He was one of the founders of the Bellevue Hospital Medical College and was its first professor of orthopædic surgery and continued to hold that chair until 1898 when the college was united with the New York University. He was then appointed emeritus professor of orthopædic surgery to the allied institutions. He was also one of the founders of the New York Academy of Medicine and of the American Medical Association, of the latter of which he became president in 1880. Dr. Sayre interested himself greatly in the sanitary affairs of New York and had much to do with the improvement of that city in this respect. But his chief reputation was acquired by his skill as a surgeon. He was the first American to perform successfully a resection of the hip for morbus coxarius in 1854, while his treatment of lateral curvature by extension and a plaster jacket is known by his name throughout the world. In 1877 he visited England for the second time as a delegate of the American Medical Association to the meeting of the British Medical Association in Manchester. He contributed largely to medical literature and was made an honorary member of the British Medical Association, the Medico-Chirurgical Society of Edinburgh, the Surgical Society of St. Petersburg and the Medical Society of Norway. Charles IV. of Sweden gave him the decoration of the Order of Wasa for his attendance on a member of the Royal Family. The *New York Medical Record*, in its obituary notice of Dr. Sayre, says: "Dr. Sayre was a typical American in every sense. Ingenious, original, and resourceful, he was ever ready to do and dare in any surgical emergency. Few in his time commanded wider and more extended appreciation of their work and no American surgeon enjoyed a better reputation than did he, whose name and fame belonged to the entire civilised world of progressive science."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Siegenbeek van Henkelom, Professor of Pathological Anatomy in the University of Leyden. A large collection of his own and his students' original researches are published under the title of "Recueil de Travaux Anatomo-Pathologiques du Laboratoire Boerhave." He was only 50 years of age.—Dr. Eugen Kotlyar of St. Petersburg, where he was *privat-docent* of Pharmacology. He also acted as editor of a journal of Practical Medicine.—Dr. Heinrich Abegg of Dantzig, at the age of 74 years. He published a number of papers, mainly on gynæcological topics, and interested himself greatly in the establishment of seaside children's homes.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In October the following candidates passed in the subjects indicated:—

Surgery.—F. G Aldrich (Section II.), Charing Cross Hospital; A. C. Clarke (Sections I. and II.), Manchester; C. J. E. Edmonds (Section II.), St Thomas's Hospital; H. Jessop (Section I.) and J. R. Pooler (Sections I. and II.); [illegible] th, St Thomas's Hospital; A. H. Wade [illegible] spital; J. Waters (Sections I. and II.) [illegible] H. F. Willington, Manchester; and T. [illegible] II.), Birmingham.

Medicine.—A. G. H. Anthonisz (Section II.), University College Hospital; J. Black and A. C. Clarke (Sections I. and II.), Manchester; J. R. Clemens, St. Thomas's and London Hospitals; F. A. Hort, Middlesex Hospital; C. Johns[illegible] London Hospital and Durham; R. A. Pitter, [illegible] Pooler (Section II.), Birmingham; F. [illegible] H. V. Swindale (Sections I. and II.), Middlesex Hospital; A. J. Watson (Section II.), St. Mary's Hospital; and T. R. Wilshaw (Section II.), Birmingham.

Forensic Medicine.—J. Black and A. C. Clarke, Manchester; J. R. [illegible]

OXFORD UNIVERSITY.—In a congregation held on Oct. 18th the following degree was conferred:—

M.D.—R. R. Wade, Exeter.

A CENTENARIAN.—The medical officer of health of Plymouth reports the death of Mrs. Preston who died on Oct. 6th, aged 102 years.

PRESENTATION TO A MEDICAL MAN.—At a smoking concert held on Sept. 28th by the members of the Wellington Lodge of Oddfellows at the Druid's Head, Oxford, Mr. W. Allin Thompson, M.R.C.S. Eng., was presented with a testimonial on the occasion of his recent retirement from the position of medical officer, after nearly 40 years' service. The testimonial consisted of a Tantalus liquor stand on which was the monogram, "W. A. T.," and an illuminated address in an oak frame, which expressed the appreciation and gratitude of the lodge for his long and skilful services.

UNIVERSITY OF CAMBRIDGE.—The following have been appointed demonstrators. Human Anatomy: Dr. F. C. Kempson and Dr. G. F. Rogers. Experimental Physics: Mr. C. T. R. Wilson, F.R.S., and Mr. J. S. E. Townsend.—The Gedge Prize for Physiology is awarded to J. Barcroft of King's and H. H. Dale of Trinity (equal).—An order has been obtained from the High Court varying the conditions for the Gedge Prize in such manner that advanced students of a certain standing are alone eligible.—The following have passed the examinations for the Public Health Diploma: J. E. Adams, J. Allan, W. S. Badger, W., R. Bhat, W. A Densham, W. H. de Wytt, J. R Garrood, H. W. G. Macleod, S. Mallannah, W. F. Moore, T Telford-Smith, G. A. Troup, J. J. Weaver, J. H. G. Whiteford, R S Williams, and R P. Wilson.—The number of students matriculating this term is 841, including 15 "advanced students." Last year the number was 888—The following examiners for medical degrees have been appointed. Physics: Mr. Fitzpatrick. Chemistry: Mr Sell, F.R S., and Mr. Adie. Biology: Mr. Bateson, F.R.S., and Mr Blackman. Pharmaceutical Chemistry: Mr. Ivatt and Mr. Purvis. Human Anatomy: Dr. Barclay Smith and Professor Wardrop Griffith. Physiology: Mr. Tuckett and Professor Starling, F.R S For the Natural Science Tripos Dr. Anderson and Professor Gotch, F.R.S., Oxford, have been appointed examiners in physiology, and Mr. Duckworth and Mr. F. G Parsons examiners in human anatomy.—The number of freshmen who have entered this term at Cambridge with the intention of pursuing a course of study for a medical degree is 115. This number may be slightly increased during the term, but it is at present somewhat smaller than last year.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—[illegible] he President and Fellows of [illegible] Ireland, held on Oct. 18th [illegible] licers were elected for the [illegible] hristopher J. Nixon, M D. R.U.I. Vice-President: Dr Joseph Redmond. Censors: Dr. Joseph Redmond, Dr. J. O'Carroll, Mr. E. H. Tweedy, and Mr. A. N. Montgomery. Additional examiners to take the place of an absent Censor—Medicine: Dr. H. C. Tweedy. Medical Jurisprudence and Hygiene: Dr. F. C. Martley. Midwifery: Dr. H. Jellett. Examiners for the [illegible] H R. Glenn and Mr. H. T. [illegible] under the Conjoint Examina- [illegible] E. MacDowel Cosgrave. Chemistry and Physics: Dr H T. Bewley and Mr. E. Lapper. Materia Medica and Pharmacy: Dr. F. J. B. Quinlan and Dr. N. Falkiner. Physiology: Dr. J. Mallet Purser. Pathology: Dr. A. C. O'Sullivan. Medicine: Dr. J. Byrnie Coleman and Dr. G. J. Peacocke. Hygiene and Forensic Medicine: Mr. W. Langford Symes. College Examiners for the Conjoint Diploma in Public Health—Hygiene: Dr. F. J. B. Quinlan. Chemistry: Professor Edwin Lapper. Meteorology: Dr. Ninian Falkiner. Examiners in Preliminary Education—Science: Mr. W. E. Thrift, F.T.C.D. Languages: Mr. William Kennedy, F.T.C.D. Representative on the General Medical Council: Dr. Lombe Atthill. Representatives on the Committee of Management under the Conjoint Examination Scheme: Dr. J. M. Finny, Sir John Moore, M.D. Dub., and Dr. James Craig. Treasurer: Dr. Lombe Atthill. Registrar: Dr. James Craig. Librarian: Mr. B. G. J. Phelps Agents to the Trust Estate: Mr. C. U. Townshend. Law Agents: Messrs. S. Gordon and Son. Architect: Mr. A. E. Murray. Dr. Martin Dempsey was admitted a Fellow of the College. In the evening the annual banquet of the President and Fellows was held in the College Hall.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADAM, T. B., L.R.C.P. & S., has been appointed House Surgeon to the Glasgow Royal Infirmary.

AINSLIE, W., M B., Ch B. Aberd., has been appointed District and Workhouse Medical Officer, Kington Union, vice R. A. Billiald, resigned.

BARNES, R., W., has been appointed Medical Officer for the No. 6 District of the Bridgwater Union, vice J. H. Jolley, resigned.

BERGIN, WM. M., M.B. Lond., M R.C S. Eng., has been appointed House Surgeon to the Royal Eye Hospital, Southwark.

BYTHELL, W. J. S., B A., M B., Ch B., has been appointed Anæsthetist to the Manchester Children's Hospital, Pendlebury.

CARTER, A. H., M.B Lond., L.R.C.P., M.R.C S., has been appointed Assistant Medical Officer to the Infirmary, Lewisham Union, vice J. Dunston, resigned.

COSENS, F. R. S., L.R C P. Lond., M.R.C.S., has been appointed District Medical Officer, Honiton Union, vice W. V. Sinclair, resigned.

CRAWFORD, G. M., M.B., Ch B., has been appointed House Surgeon to the Glasgow Royal Infirmary.

DOUGLAS, JOHN C., L.R.C P. & S., has been appointed House Physician to the Glasgow Royal Infirmary.

FERGUSSON, H. C., M B., Ch B., has been appointed House Surgeon to the Glasgow Royal Infirmary.

FINDLAY, LEONARD, M.B., Ch.B., has been appointed House Physician to the Glasgow Royal Infirmary.

FORMAN, BERNARD GILPIN, M.B., Ch.B Edin., has been appointed Assistant House Surgeon to the Dumfries and Galloway Royal Infirmary.

GARROW, A., M.B., Ch B., has been appointed House Surgeon (Ophthalmic) to the Glasgow Royal Infirmary.

GUNSON, CHARLES HERBERT, M.B., Ch.B. Glasg., has been appointed Resident Surgeon to the North Cambs. Hospital, Wisbech.

HARRINGTON, A. W., M B., Ch.B., has been appointed House Physician to the Glasgow Royal Infirmary.

HIGHMOOR, R. N., C M. Edin., has been appointed Medical Officer for the Fransham Sanitary District of the Mitford and Launditch Union, vice R. E. Newton, resigned.

HOBART, N. H., M.B., B S Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer, Cork North Infirmary, vice N. J. Hobart, resigned.

LEITCH, J. W., M B., Ch.B., has been appointed House Surgeon to the Glasgow Royal Infirmary.

LEYS, NORMAN M., M.B., Ch B., has been appointed House Physician to the Glasgow Royal Infirmary.

McDONALD, ELLEN S., L.R C P. & S., has been appointed House Surgeon (Gynæcological) to the Glasgow Royal Infirmary.

MONTGOMERY, W. P., M.A Oxon., B S., M.B. Lond., F.R.C.S. Eng., has been appointed an Honorary Assistant Surgeon to the Royal Infirmary, Manchester

NAISMITH, J. H., M.B., M S Glasg., has been appointed Medical Officer of Health for the Tow Law Urban Sanitary District, vice W. Tiplady, resigned.

[illegible] M S. Irel., has been appointed Assistant [illegible] orkhouse of the Parish of Nottingham, [illegible] ied

RAINFIRD, P. H., [illegible], has been appointed House Surgeon to the Glasgow Royal Infirmary.

ROBERTS, EDWARD W., M R.C S., has been appointed House Physician to the Glasgow Royal Infirmary.

Russell, Matilda H. G., L.R.C.P., L R C S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer to the Infirmary of the Parish of St. Giles, Camberwell, vice Miss L. G. Anderson, resigned.

Scott, J. H, M.R C.P., L.R.C.S. Irel, has been appointed District Medical Officer, Eton Union, vice T. Miller, resigned.

Simmons, S. S., L R.C.P. Lond, M.R.C.S., has been appointed District Medical Officer, Croydon Union, vice T. R. B. Parker, deceased.

Smith, H. Oswald, M B., Ch B, has been appointed House Surgeon to the Glasgow Royal Infirmary.

Thomson, R. S., B Sc. Glasg., M D., has been appointed Professor of Practice of Medicine, Anderson's College Medical School, Glasgow.

Watson, A. L, M.B, Ch B, has been appointed House Surgeon to the Glasgow Royal Infirmary.

Wild, R. B., M.Sc. Vict., B.Sc., M.D. Lond., has been appointed an Honorary Physician to the Cancer Pavilion and Home connected with Owens College, Manchester, vice D. J. Leech, deceased.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead and Wirral Children's Hospital, Woodchurch-road, Birkenhead.—House Surgeon for twelve months. Salary £100 per annum, with board, residence, and laundry.

Chelsea Hospital for Women, Fulham-road, S.W.—Assistant Anæsthetist. Medical women eligible for the post.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150 by £10 annually, with board, furnished apartments, &c.

County Asylum, Chester.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board (no liquors), lodging, and washing.

Down District Asylum Downpatrick.—Assistant Medical Officer, unmarried. Salary £150, rising £10 annually to £200, with furnished apartments, board, washing, and attendance. Apply to the Resident Medical Superintendent.

Dundee Royal Lunatic Asylum.—Medical Assistant.

French Hospital and Dispensary, 172, Shaftesbury-avenue, London.—Resident Medical Officer (not a female), registered, speaking French, and unmarried. Salary £80 a year, with full board.

Guest Hospital, Dudley.—Assistant House Surgeon for six months. Salary at the rate of £40 per annum, residence, board, and washing.

Herefordshire Rural District Councils.—Medical Officer of Health for the Combined Districts for three years. Salary £530 per annum including expenses and disbursements. Apply to the Clerk, Hereford.

Hospital for Diseases of the Throat, Golden-square, London.—Four vacancies for the office of Senior Clinical.

Hospital for Sick Children, Great Ormond-street, London.—Ophthalmic Surgeon.

Jarvis' Charity, Staunton-on-Wye, Hereford.—Medical Officer, to reside in house provided by the Trustees, with garden and good stabling rent free. Salary £150 per annum and certain allowances.

Jenner Institute of Preventive Medicine, Chelsea Gardens, London.—Assistant in the Department of Pathological Chemistry. Salary £300.

Kent County Asylum, Chartham, near Canterbury.—Second Assistant Medical Officer, unmarried Salary begins at £175 per annum, with board, quarters, washing, and attendance. Also Third Assistant Medical Officer required in January next. Salary begins at £125, with emoluments as above.

London Temperance Hospital, Hampstead-road, N.W.—Resident Medical Officer for one year. Salary £200 per annum, with board, lodging, and washing.

Leeds General Infirmary.—Resident Obstetric Officer. Board, lodging, and washing provided. Also two House Physicians for six months Board, lodging, and washing provided.

Northumberland County Asylum, Morpeth.—Assistant Medical Officer, unmarried Salary £125 per annum, rising £10 yearly to £155, with board, lodging, and washing.

North London Hospital for Consumption, Hampstead.—Senior and Junior Resident Medical Officers for twelve months. Honorariums £100 and £60. Apply to the Secretary, Offices, 41, Fitzroy-square, W.

Parish Council of Tingwall Whiteness, and Weisdale.—Medical Officer Salary £40 per annum, which includes the cost of medicine for paupers belonging to the parish. Apply to the Inspector of Poor, Scalloway, Shetland.

Parish of St. Matthew, Bethnal Green, London.—Clinical Assistant at the Infirmary, Cambridge-road, N.E, for six months, unmarried. Salary at the rate of £40 for the six months, with board, lodging, and washing. Apply to the Medical Superintendent of the Infirmary, Cambridge-road.

Royal Albert Hospital, Devonport.—Assistant House Surgeon for six months. Salary at the rate of £40 per annum, with board, lodging, and washing.

Royal College of Surgeons, Edinburgh.—Conservator to the Museum. Salary £105. Apply to the Clerk of the College, 54, George square, Edinburgh.

Royal Infirmary, Sheffield.—House Physician. Salary £100 per annum, with board, lodging, and washing.

Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, Isle of Wight.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging in the hospital. Apply to the Secretary, London Office, 34, Craven-street, Charing-cross, W.C.

Royal Sea Bathing Hospital, Margate.—Resident Surgeon. Salary £100, with board and residence. Apply to the Secretary, Royal Sea Bathing Hospital, Offices, 30, Charing-cross, London.

South Devon and East Cornwall Hospital, Plymouth.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

Southport Convalescent Hospital and Sea Bathing Infirmary.—Resident Medical Officer, unmarried. Salary to commence at £150 per annum.

The Chief Inspector of Factories gives notice of vacancies as Certifying Surgeons under the Factory Acts at Diss, in the county of Norfolk; at Broughton Astley, in the county of Leicester; and at Rahan, in King's County.

Wolverhampton Eye Infirmary.—House Surgeon for twelve months. Salary £70 per annum, with rooms, board, and washing.

York Dispensary.—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

Blumer.—On Oct. 19th, at St. Mary's-grove, Stafford, the wife of F. Milnes Blumer, M.B., of a son.

Brock.—On Oct. 14th, at Via Veneto, B, Rome, Italy, the wife of G. Sandison Brock, M.D., of a daughter.

Drury.—On Oct. 21st, at Grahamstown, South Africa, the wife of Edward Guy Dru Drury, M.D., B.S. Lond., of a son. (By cable.)

Kent.—On Oct. 19th, at Dorset Cottage, Bexhill, the wife of Sydney Kent, M.B., B.C. Cantab., M.R.C.S., L R.C.P., of a son.

Newnham.—On Oct. 21st, at Chandos Villa, Queen's-road, Clifton, Bristol, the wife of W. H. C. Newnham, M.A., M.B. Cantab, of a daughter.

Turner.—On Oct. 16th, at Plympton House, Plympton, South Devon, the wife of Alfred Turner, M.D. Edin., of a son.

Williams.—On Oct. 17th, the wife of Watson Williams, M.D., Victoria-square, Clifton, Bristol, of a daughter.

Withers.—On Oct 17th, at Ashford, Peel-causeway, Cheshire, the wife of Percy Withers, M.B., B.S., of a daughter.

MARRIAGES.

Gervis—Stirling.—On Oct. 24th, at the Parish Church of St. Alfege Greenwich, Charles Berkeley Gervis, M.D., of Seaford, to Grace, youngest daughter of Thomas Stirling, of 13, Gloucester-place, Greenwich.

Scott Wilkinson—Bell.—On Oct. 20th, at St. Mark's Church, Kennington, by the Rev. Mr. Bankart, Charles Scott Wilkinson, son of Adam Wilkinson, M.D., J.P., of Avishayes, Shaftesbury, Dorset, to Frances Dorothy, eldest daughter of John Bell, Esq, of Newcastle-on-Tyne.

Tyrrell—Livesey.—On Oct. 17th, at St. Peter's, Eaton-square, Charles Robert Tyrrell Major Royal Army Medical Corps, to Agnes Laura, youngest daughter of James Livesey, Esq., of Grosvenor-gardens, S.W., and Rotherfield, Sussex.

Wood—Harris.—On Oct. 17th, at Littleham Church, Exmouth, Thomas Wood, J.P. for Midlothian, M.B., C.M. Edin, youngest son of the late William Inglis Wood, Lindores, Newburgh, Fife, to Alice Elizabeth Esther, daughter of John Harris, St. Mary's Lodge, Exmouth.

DEATHS.

Brown.—On Oct. 17th, at Holly Lodge, Brockley-road, S.E, Alexander Stewart Brown, F.R.C.S., aged 45 years.

Eccles.—On the 22nd Oct, suddenly, at 23, Hertford-street, Mayfair, W. Arthur Symons Eccles, M.B., C.M., in his forty-sixth year.

Reynolds.—On the 20th inst., at Southend-on-Sea, Edward Robert Bradley Reynolds, M R C.S. Eng., of Highcroft, Shepherd's Hill, Highgate, and late of Highbury New Park, N., aged 65.

Wood.—On Oct. 16th, at St. John-street, Oxford, William Dyson Wood, L.R C.P., L.R.C.S. Edin, Medical Officer of Health for the County of Oxford.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE STUDENTS AND THE FAITH-HEALER.

THE disturbances created by medical students and other young men at certain lectures given by a crack-brained adventurer calling himself "Overseer of the Church in Zion" were what might have been expected. Becky Sharpe, it may be remembered, remarked *apropos* of her throwing back the "Dixonary," "Revenge may be wicked but it's natural." The same may be said of the proceedings of the students. Dowie, judging from the papers which he edits, "for the extension of the kingdom of God," is a person who combines a nauseous profession of religion with the practice of quack medicine as a faith-healer. He has been called by at least one newspaper neither more nor less than a swindler. It is only natural that medical students hearing their profession abused and their teachers insulted should mark their disapprobation of Dowie, though it is to be regretted that they should do so by acts which are illegal. It would of course have been much better policy to leave Dowie alone. Pretenders of all kinds are far more hurt by being ignored than by anything else and if Dowie has paid for the use [illegible] certain of the culprit and the [illegible] examples were required we think that under the circumstances the students have had hard lines.

A CURIOUS TRANSACTION.

To the Editors of THE LANCET.

SIRS,—I shall esteem it a favour if you will kindly state your opinion upon the following transaction. A purchased a practice (a country branch) from B, a certain sum of money being paid down, the remainder to be paid in a manner mutually agreed upon. In the [illegible] A understood was to be trans- [illegible] made between A [illegible] informed by *one of the members* of the club in question that he, A, was not to be the medical attendant, another practitioner, C, having been appointed, as B had tendered his resignation. This statement led A to make inquiries into the matter, when he found that B had resigned the appointment, and was merely working out the stipulated term of notice between himself and the club. As this notice was given *prior* to the actual purchase of the practice by A, he naturally feels that he has been very unfairly dealt with by B, who gave him no information whatever about the matter. A called upon B in order to talk matters over and, if possible, to come to a friendly arrangement, but the latter acted in a most high-handed manner and refused to discuss the subject. I may here mention that C is a practitioner residing in the same town as B, with whom he is on intimate terms. Under the circumstances ought not B to allow A a certain sum, to be agreed upon, in consideration of transferring an appointment which he had resigned prior [illegible] to have cited in [illegible] information upon t[illegible]

Oct. 22nd, 1900. ALPHA.

*** If B has purported to sell to A a club practice which it was no longer in his power to sell—the practice having been transferred to C—A is clearly aggrieved, and will be right to take such steps as his solicitor may recommend to obtain justice. We have only "Alpha's" statement before us, which seems to be written from A's point of view. We cannot speak more definitely without hearing B's account of the transaction.—ED. L.

WANTED—A HOME

To the Editors of THE LANCET.

SIRS,—I would be much obliged if any of your readers could tell me of a home where I could send a poor woman suffering from complete paralysis with some cerebral symptoms. We would be willing to pay about from 15*s* to £1 per week for her. I should be very grateful for the information.

I am, Sirs, yours faithfully,

Oct. 21st, 1900. PHYSICIAN.

COAL SMOKE ABATEMENT.

THE New London Brewery Company, Limited, of Vauxhall, were summoned by the Lambeth Vestry last week for "sending forth black smoke from the chimney shaft of their premises in such quantities as to be a nuisance." Inspector Perrin, for the vestry, testified that on August 2nd he watched the chimney shaft at the defendant company's premises for several hours. Dense black smoke issued at intervals for a period of 33 minutes. The officer added that in April last the defendants were similarly summoned and fined by Mr. Hopkins. It was urged, in mitigation of penalty, that every effort had been made to subdue the smoke, and an apparatus had been just introduced which it was thought would prove effective. Mr. Shell said he should inflict the full penalty of £10, adding that in his opinion the law was not strong enough on this matter. His worship, we think, does not do himself or the law justice. The law is all right but it wants setting in action and magistrates like himself to see it carried out.

"DIFFICULTIES UNDER THE INFECTIOUS DISEASE NOTIFICATION ACT."

To the Editors of THE LANCET

SIRS,—I have been reading the little book, "Difficulties Under the Infectious Disease (Notification) Act" and on p. 22 I find that there has been some question raised as to whether medical officers of health should be paid for notifying cases where they are the medical attendant. If you refer to Section 11 of the Act you will there find that there is no doubt on the matter whatever, as it is distinctly stated that they are to be paid the fee "to which he would be entitled as if he were not such medical officer."

I am, Sirs, yours faithfully,
R. E. BURGES, M.D. R.U.I.,
Medical Officer of Health, Hoole Urban District, Cheshire.
Chester, Oct. 11th, 1900.

A MIDWIFE FINED FOR GIVING A FALSE BIRTH CERTIFICATE.

AT the South-Western Police Court, Sarah May Bellinger, a certificated midwife, of 38, Carpenter-street, Battersea, was fined £2 15*s*., including costs, on Monday last, for giving a false certificate relating to the birth of a child. Mr. Lewis prosecu[illegible] ceedings being instituted at the insti[illegible] the coroner for the South-Western division of London. Mr. Braxton Hicks is to be congratulated upon the stand he has taken in this matter. If a certificate concerning a birth or a death is to be any safeguard to the public it must be given with all proper circumspection and in accordance with proper legal restrictions. It is gratifying to know that the coroner has been much assisted in his work against irregular certificates by the burial authorities and undertakers, for these officials have in other times and places been far too easy-going.

ADHESIVE PLASTER FOR PUNCTURED TYRES.

To the Editors of THE LANCET.

SIRS,—I should be glad to hear if any of your readers who happen to be cyclists have tried any adhesive plaster for mending punctured bicycle tyres and what success has attended them.

I am, Sirs, yours faithfully,

Oct. 23rd, 1900. CYCLIST.

A POINT IN LUNACY POOR-LAW.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will tell me through your columns whether a magistrate may give a detention order for any person of unsound mind to be detained "not more than 14 days" in a workhouse *without a medical opinion or certificate.* The relieving officer here considers that my certificate is not necessary if the magistrate forms his own opinion as to the lunacy. Besides seeming to me a relaxation of the safeguards for lunatics against wrong detention I do not mind admitting that it is also a question of fees, the responsibility in any case practically resting upon me. I have to thank you very much for your opinion given in other cases and shall be much obliged if you can answer this case.

I am, Sirs, yours faithfully,

Workhouse, Hampstead, Oct. 22nd, 1900. B. CLAUDE TAYLOR.

*** The action of a lunacy justice in signing a 14 days' detention order without first summoning a duly qualified medical practitioner to examine and report upon the alleged lunatic is distinctly *contra legem.* The Act expressly directs that the justice shall summon a medical practitioner to his aid and shall then proceed to examine the lunatic. The first thing which the justice has to do is to summon a medical man to examine the case. In strict law the justice cannot even visit the alleged lunatic without the medical man, though it is not usual to raise any objection to his doing so if he wishes, but to sign any order for detention is contrary both to the spirit and to the letter of the law. It is a common error for a justice new to the work, to think that he is only obliged to summon a medical man in cases which he, the justice, deems to be of unsound mind, but this is not so. His first step is to summon a medical man to his aid who reports to the justice his opinion on the case and upon that opinion only can he take any action. The medical man receives his fee for reporting upon the case whether [illegible] for removal or whether [illegible] discharged or, thirdly, [illegible] under a 14 days' detention order. In any case, he receives his fee for the report and not for certifying the alleged lunatic to be either of sound or of unsound mind. Our correspondent, therefore, is correct in the first part of his letter, but he is not correct in presuming that he has any responsibility unless he is summoned by the justice. He is not responsible for the justice's ignorance of the law. This is a question for the Lunacy Commissioners or for the medical superintendent of the asylum to which a certified lunatic is removed. —ED. L.

An Address

ON

THE SURGERY OF THE STOMACH.

WITH ILLUSTRATIVF CASES

Delivered at the Victoria Infirmary Glasgow, on Feb 22nd, 1900, before the Glasgow Southern Medical Society,

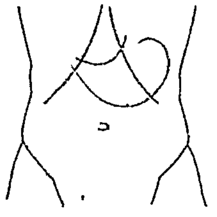
By A ERNEST MAYLARD, B S , M B Lond ,
SURGEON TO THE VICTORIA INFIRMARY GLASGOW EXTERNAL EXAMINER IN SURGERY TO THE VICTORIA UNIVERSITY, MANCHESTER

Gentlemen —Of all the invasions which practical surgery has made into the domain of medicine, certainly one of the most important, if not the last encroachment within recent years, has been that upon the stomach Great, too, as has been the advance in this direction, it must be still owned that we are but on the threshold of a field of labour replete with prospects both hopeful and encouraging I do not propose to occupy the brief time at my disposal in tracing the origin and development of this comparatively new and interesting departure in surgery, however instructive such an investigation would prove, sufficient will it be if I can give you some concise idea of what at present we are able to accomplish and what we still further hope to do in the not distant future

Before, however, dealing with the essentially practical side of my subject let me ask your attention for a few minutes while I strive to disperse some of those erroneous impressions which are still illustrated in our anatomical text-books, and, indeed, still linger in the minds of many surgeons, of the true position of the stomach in the abdomen You will observe by looking at the diagram (see Fig 1) taken from one of our most popular text books on anatomy that the stomach is made to assume a transverse position—in other words, the cardiac orifice is only slightly above the pyloric and the long axis of the viscus is almost transverse to the trunk of the body Now look at this diagram (see Fig 2) which may be taken as approximately representing the normal disposition of the organ The lesser curvature, instead of, as in the last diagram, looking upwards is here seen to be directed mostly towards the right, while about four fifths or even seven eighths of the viscus is to the left of the middle line That this must be the normal position of the stomach in health is sufficiently attested by these facts first that the cardiac orifice is situated about opposite to the junction of the seventh costal cartilage with the sternum, and that the pylorus—as I have frequently demonstrated—lies from two to three inches below the ensiform cartilage and from an inch to an inch and a half to the right of the middle line Hence if you draw a line, curved somewhat to the left from an inch to the left of the middle line above opposite the junction of the seventh costal cartilage with the sternum to a point about three inches below the ensiform cartilage and an inch to the right of the middle line, you will get a line that is much more vertical than transverse, and, further, if you allow that the stomach rises for about an inch or so above

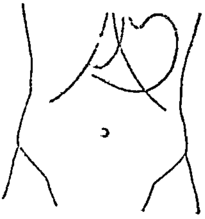
[illegible]
you will see how very much of
n occupies the left side of the
at the erroneous transverse dis
so long dominated our minds
has doubtless arisen from the position of the organ as found
in the dissecting room and
The relaxation of the diaphr
loss of all those supporting
life are quite sufficient to
and situation of the stomacl
has come to be an *in situ* object of observation and investigation during life we have learnt to regard it from a new aspect and a more correct one I should not have deemed it worth while directing your attention so forcibly to this
little piece of norm
that in two sets (
A E J Barker¹ ,
diagrams given to
erroneous type The stomach in each set of illustrations is made to appear as if it lay transversely across the right hypochondriac, epigastric, and left hypochondriac regions

FIG 1



Erroneously assumed position of the stomach.

FIG 2



True position of the stomach

If, then the normal position of the stomach be such as I
have described to you it has to
tion is very materially affecte
or indirectly connected with it
may drag it downwards adhesions contracted to other parts may displace it in almost any direction, while obstruction seated at one or other orifice may cause it to become either enormously increased in size and capacity or greatly diminished Notwithstanding, however, all these changes, the result of disease, there is a value, and that of increasing importance, in a correct knowledge of the normal position of the stomach For if there is one line more than another in which our desires lie, it is in early exploratory operations where we may hope to treat certain diseased conditions long before they have reached those hopelessly advanced stages with which we are at present only too familiar, and before therefore, the stomach has been altered in shape or position

I now pass from these few remarks upon the anatomy of the stomach to consider the various operations which we are prepared to perform upon it I shall simplify this consideration in the first instance by placing before you a detailed list of these operations so far as they are at present carried out by the operating surgeon You may take the following list of operations as a fairly comprehensive and complete
one (1) gastrotomy , (2) gastrc
gastroplication , (4) gastrectomy
gastrolysis ; (6) gastroplasty ,
gastropexy , (9) pylorectomy , (
method and by the submucous
sion from within (Loreta) and
gastro duodenostomy , a
(Woelfler) and posterior
(14) gastro jejunostomy
(15) pylorectomy with gastro jejunostomy , and (16) division of the jejunum with implantation of the distal end into the stomach and the proximal end into the jejunum It would carry me far beyond the time at my disposal to enter at any descriptive length into the performance of these various operations, not to speak of the many variations in method of execution which several of them admit I shall sufficiently reach the ends I have in view by casting comparatively rapidly on to the screen a series of outline sketches which will indicate the essential features of each operation The principal object for which I strive this evening is to show for what practical ends we propose to employ each operation, or in other words, what diseases of the stomach we may hope in some instances to alleviate in others to cure And, further, I particularly wish to show the results of some of the operations as seen in such patients as I can introduce to you, and in the records of such others as for various good reasons I cannot personally exhibit I may say in passing that the cases which I bring before you to night are the result of the last 15 months' personal work in this particular department of surgery, and I include every case upon which I have operated, but time forbids my alluding to many other interesting cases which I have seen I now take up the first operation, that of

---

[2] Brit. Med Jour, 1900, vol. i. p 241

GASTRECTOMY.

I now ask your attention to the operation of gastrectomy. I do not intend to enter at any length into the steps of the operation either in its partial or complete form. A few words, however, on the "complete" operation and its results in view of the comparative novelty of the procedure will not be out of place. The entire stomach has now been successfully removed some half-a-dozen times and with the remarkable result that not only have the patients been relieved of much suffering but they have really been none the worse through the loss of an organ which, it has been assumed, fulfils such an important rôle in the function of digestion. Schlatter's remarkable case, which was so elaborately investigated for a lengthened period after the operation by expert physiologists and chemists, tended to show that the nutritive and metabolic processes of the system were but very slightly interfered with; indeed, all that was required for necessary digestion and absorption seemed to be efficiently carried out by the intestines. It may, therefore, be that we shall have to re-construct our theories on the hitherto supposed principal functions of the stomach and attach more importance to its rôle as a storage receptacle for the gradual and continuous discharge of nutrient material into the intestine, while at the same time it allows of the convenient intermittent ingestion of food.

As regards the practical part of the operation it will only be in exceptional cases that it will be found possible to unite the divided duodenum to the cut end of the œsophagus, as was successfully accomplished by Childs-Macdonald of San Francisco with Murphy's button. In most instances the œsophagus must be implanted into a loop of the jejunum, as in Schlatter's case. I have tried several times on the cadaver to approximate the duodenum to the gullet, and in the healthy state of the parts it is certainly rarely possible. The perpetual dragging effect, however, of a stomach weighty from its involvement in tumour growth tends to give a laxity and mobility to the first part of the duodenum which otherwise does not always exist in the normal healthy state. I shall say nothing upon the merits or demerits of the operation for extensive disease of the stomach. It is a very severe one, and the extreme gravity connected with its performance, together with the very doubtful nature of the result which may follow, must be well weighed with other considerations affecting the present sufferings of the patient and his future prospects of life if nothing is attempted.

GASTROLYSIS.

Upon the operation of gastrolysis and the condition for which it is practised I have not much to say. From various causes, but more particularly from gastric ulcer and gall-stones, adhesions form between the stomach and neighbouring parts. These adhesions may either so restrict and drag upon the viscus as to interfere with its normal contraction, or they may fix it in such a position as to cause obstruction. This latter derangement usually happens when the pylorus is involved It may be either kinked or contracted. The symptoms associated with adhesions naturally vary according to the organic effect which they produce. Those which result from obstruction are of a nature similar to what follows upon obstruction arising from other better recognised sources and are often quite indistinguishable from them. On the other hand, symptoms arising from some impediment to normal contractile functions of the organ are often of a very obscure and obstinate character. It is only from the past history of the case—that is to say, some antecedent symptoms of ulcer or gall-stone—that the probable cause can be arrived at. This, indeed, is a class of cases where an exploratory laporatory has frequently effected the very best results, for the discovery of adhesions and their division with consequent liberation of the stomach have afforded complete and permanent relief. I have only one case in my present list which illustrates this condition. I shall refer to it more fully under the operation of gastro-jejunostomy; but I may briefly remark here that the adhesions, which were partially liberated, existed mostly between the pylorus and the under surface of the liver. They were the result, as we discovered after an exploratory gastrotomy, of an old healed ulcer Surgery, then, has done much in recent years by the operation of gastrolysis to relieve and to cure various cases which were hitherto vague in their symptoms and absolutely intractable to all forms of medical treatment

I must here break away from the order in my list of operations, as time forbids my referring to all contained in it, and more especially also as I wish to direct some particular attention to the operation of

GASTRO-JEJUNOSTOMY.

This operation may now be regarded in practical hands as a comparatively simple and safe one, and its employment is becoming widened to the extent of replacing such operations as divulsion of the pylorus, pyloroplasty, and pylorectomy for cicatrical contraction of the pylorus. Its service in malignant disease of the stomach, whether of the body or the pylorus, is well recognised, and its value in the treatment of gastric ulcer and gastric erosion associated with hæmorrhage is [illegible] appreciated. There is no reason to [illegible] employment in uncomplicated cases of gastric ulcer—such, for instance, as are intractable to treatment and by their prolonged continuance dangerous to life—is within the field of early recognition. I am able to bring before you this evening the records of six cases which I have operated upon within the last eight months. Five were successful, one was fatal; of the five I can show you two patients. The brief histories of these cases were as follows, and I narrate them before discussing anything further in regard to the operation itself.

CASE 4. *Cicatricial stricture of the pylorus; exploratory gastr[illegible] l gastro jejunostomy; death from* [illegible] 35 years, was sent to me by [illegible] lexandria, Dumbartonshire, and was admitted to the Victoria Infirmary on Sept. 28th, 1899. His symptoms apparently dated from about 15 years previously and at the time of my seeing him were evidently due to obstruction at the pylorus. On Oct. 4th the abdomen was opened by a median incision above the umbilicus. Manipulation of the pylorus externally revealed a resistant induration extending along the lesser curvature. On opening the stomach and inserting the index finger a contracted, somewhat irregular orifice was felt, admitting the passage of a No. 12 catheter but not capable of distension by moderate pressure of the finger. The exploratory incision was then closed and a posterior gastro-jejunostomy was performed, the union between the bowel and the stomach being effected by Murphy's button. The dilated stomach was lessened by first doubling in and securing one pleat of the anterior wall and over this inserting a second series of Lembert sutures so as to fold more deeply in the wall and approximate the lesser and greater curvatures. The patient rallied well from the operation and subsequently took milk-and-soda and passed flatus. He, however, soon began to show signs of failing strength and he died on the fourth day apparently from exhaustion. At the post-mortem examination the most marked feature found was the want of union between the opposing halves of the button and also the lack of union between the stitched walls of the stomach and other lines of suture. There was no general peritonitis but some suspicious appearance of recent inflammation in the region of the button. The pylorus was found to be contracted by a cicatrix, the result apparently of an old healed ulcer. I attribute the fatal result in this case largely to the very low recuperative powers possessed by the patient. He had been a chronic invalid for so many years that his tissues were in a poverty-stricken condition and incapable of exercising the necessary reparative powers for recovery after such an operation. It was, however, disappointing to lose the patient, because the operation was just the one to have given him permanent relief.

CASE 5. *Exploratory gastrotomy: gastro jejunostomy for inseparable adhesions of the stomach to the liver, the sequel to chronic ulcer; recovery.*—A patient of Dr. W. Grant of High Blantyre, aged 45 years, was sent to me at the Victoria Infirmary on May 24th, 1899. About three years ago he commenced to complain of gastric symptoms which on admission were those of obstruction at the pylorus. On May 31st the abdomen was opened by a median incision above the umbilicus. Fibrous adhesions were at once encountered uniting the stomach to the under surface of the liver on the right side. These were ligatured and divided, when an exceptionally dense and intimate band of union was reached forbidding any attempt at separation. The stomach was opened to ascertain if possible the nature of this indurated mass. It was then found that an irregular-shaped ulcer with elevated but smooth edges existed in the lesser curvature about an inch from the pylorus. Its floor was deeply indented and it extended well up into the liver substance. Any attempt at liberation of the stomach being deemed inadvisable, the exploratory gastrotomy wound was closed and a posterior gastro-jejunostomy was performed, union between the stomach and bowel being effected by Murphy's button. The patient made a comparatively uninterrupted recovery. The button was passed on the eleventh day. One month afterwards he had put on nine pounds in weight, and was in good health and able to take food well. As you see him at the present—that is, nine months after the operation—he is in perfect health, taking his food well, and is at his work.

CASE 6.—*Carcinoma of the pylorus; gastro-jejunostomy; recovery.*—The patient, a woman, aged 63 years, was admitted to the Victoria Infirmary on July 13th, 1899. For some months she had been failing in health, but it was only four months ago that she commenced to be troubled with symptoms of pyloric obstruction. On July 21st the abdomen was opened in the middle line above the umbilicus. A tumour was detected well under the liver to the right involving the pylorus and intimately adherent to the fundus of the gall-bladder. It was of about the size of an orange and somewhat nodular in outline As the liver showed no signs of infection an attempt was made to perform pylorectomy. It was soon discovered, however, that numerous infected glands existed, passing upwards to the transverse fissure of the liver. Any further attempt at extirpation was therefore abandoned. A posterior gastro-jejunostomy was performed, union between the stomach and the bowel being effected by means of Murphy's button. With the exception of a little temporary bronchitis the patient made an uninterrupted recovery. She left the infirmary on August 16th, three and a half weeks after the operation, with the wound soundly healed. The button had not been passed. On Oct. 20th, three months after the operation, the patient presented herself. She stated that for some weeks after the operation she had improved greatly in strength and that she took her food well. Whatever she took kept down and she had never been troubled with vomiting As far as she knew the button had not passed. On Jan 8th, 1900, her daughter visited the infirmary and reported that her mother was in a very low state of health with swollen legs and failing, she thought, rapidly. The button had never been seen. She died from exhaustion on Jan. 18th

CASE 7.—*Gastro jejunostomy for extensive malignant disease of the pylorus and the pyloric region; recovery.*—In this case the man who was operated upon was 57 years of age and was a patient of Dr Ross Carmichael of Cathcart, with whom I saw him in consultation on Oct. 11th, 1899. For two years the patient had suffered from some obscure gastric symptoms manifested mostly by distaste for food. For the last 18 months he had vomited and had manifested other symptoms of pyloric obstruction. On Oct. 19th the abdomen was opened. A tumour of considerable size occupied the pylorus and the right portion of the stomach. It was very smooth in outline but the margins of it, as felt along the anterior wall of the stomach, were lobulated. The growth was found to be adherent to the under surface of the liver Excision not appearing feasible a posterior gastro-jejunostomy was performed with some difficulty owing to the extent to which the disease had reached along the fundus towards the left. Union was effected by Murphy's button. The patient made an uninterrupted recovery, taking his food without pain and putting on 10 lb. in weight in the course of three weeks The button was passed on the twelfth day. I heard recently that this patient had commenced vomiting again. I fear that the explanation is due to the invasion of the artificial orifice by the growth.

CASE 8 *Carcinoma of the body of the stomach; gastro-jejunostomy; recovery.*—A man, aged 54 years, was admitted to the Victoria Infirmary on Jan 4th, 1900. Nine months ago he commenced to feel a lack of energy which he had never experienced previously. He lost relish for his food and began to lose flesh. About this time or a little later he felt a burning sensation in the stomach which was often slightly relieved after the ingestion of food. On Jan 13th the abdomen was opened by a median incision, exposing at once the tumour, which appeared like a large crescentic mass occupying the left portion of the body of the stomach, involving mostly the posterior wall and approximating at its centre the two curvatures. The liver appeared to be free from infection but enlarged glands existed in the lesser omentum. Excision of the tumour was abandoned owing to the infection of the lymphatic glands and a posterior gastro-jejunostomy was with some difficulty performed. Union between the stomach and the bowel was effected by means of Murphy's button. The operation lasted an hour. There were no subsequent untoward symptoms, but recovery was greatly retarded by some stitch abscesses. At this date he is still an inmate of the infirmary but is well enough to get about and although it is about six weeks since the operation the button has not been passed. He now takes his food well and is feeling much relieved of some of his original symptoms.

CASE 9. *Carcinoma of the pylorus; gastro-jejunostomy; recovery.*[5]—The patient a man, aged 60 years, who had been under the care of Dr. Fraser Orr, with whom I saw him in consultation, was admitted to the Victoria Infirmary on Feb. 17th, 1900, suffering from gastric symptoms of obstruction at the pylorus. On Feb. 27th the abdomen was opened. Extensive disease of the pylorus was discovered with small nodules of tumour in the matted tissue around. The growth extended for about two and a half inches along the lesser curvature No attempt was made to perform pylorectomy. A posterior gastro jejunostomy was executed with the aid of a Murphy's button. As only a week has elapsed since the operation it is not possible to say much except that from the absence of all symptoms the patient seems to be in a fair way towards perfect recovery.

In reviewing briefly some of the special points of interest in these cases you will observe, in the first place, that I performed in all of them a posterior gastro-jejunostomy, effecting the union between the stomach and the bowel by means of a medium-sized Murphy's button. The more I practise this particular method of performing gastro-jejunostomy with the button the more I like it, and I can quite appreciate Czerny's recent opinion regarding it, that he prefers it to all others. Although the chief object of gastro jejunostomy, by whatever method performed, is to admit a free exit of the gastric contents into the intestine, I am convinced that the operation subserves, in many cases, a not less important part in giving rest to the organ This is the explanation of its great good in gastric ulcer, associated or not with hæmorrhage. Instead of the food being churned up and constantly moved about by the normal contractions of the stomach it passes rapidly into the bowel and so the organ is at rest again and in the best possible condition for repairing internal lesions. I believe the very material relief afforded in the last case just shown you (Case 8)—in which, as you will remember, the patient had no signs of obstruction but in which a large malignant tumour occupied the body of the stomach—was due to the rest afforded the organ by the operation removing sources of constant irritation.

I must not, gentlemen, be tempted to discuss other points, many and interesting as they are, in connexion with this operation I fear that I have already overtaxed your indulgence The subject which I have selected this evening is an extensive one and is becoming increasingly so, and I have found not a little difficulty in condensing within a reasonable space and still more within a limited time such material as that which I wished to present to you. The following table will briefly indicate the operations which I have performed since January, 1899:—

*Table of Operations upon the Stomach.**

Operation.	Disease	Recovery	Died.	Total
Exploratory gastrotomy.	Extensive adhesions, &c.	3	—	3
Gastrostomy.	Carcinoma of the gullet.	5	1†	6
Gastrorrhaphy.	Perforated gastric ulcer.	2	—	2
"	Dilated stomach.	2	—	2
Gastro-jejunostomy.	Cicatricial stricture of the pylorus.	2	1	3
"	Malignant stricture of the pylorus	6	—	6
"	Carcinoma of the body of the stomach.	1	—	1
Pylorectomy.	Carcinoma of the pylorus.	1	—	1
—	—	22	2	24

---

* This table originally contained only the operations performed within the period of 15 months from which the cases were taken for the address I have, however, now added those executed since that date, so that the table at present represents the total number of operations performed upon the stomach within the last year and ten months—i e., down to Oct. 31st, 1900.

† The death on the fifth day in this case was unconnected with the

---

[5] This case occurred a few days after the delivery of the address, but as the opportunity is afforded it seems worth while to record it.

operation and due to increasing exhaustion from the very extensive disease present.

I must not conclude without acknowledging the valuable help which I have received in most of the above operations from my assistant colleague Dr. Grant Andrew, and from Dr. D. Lamb, the anæsthetist to the infirmary. To have a complete sense of reliance on one's right hand coöperator and to be relieved of all feeling of anxiety regarding the administration of the anæsthetic are, indeed, means in the performance of any grave operation which contribute in no small way to successful results.

Inaugural Address

ON

BACTERIOLOGICAL DIAGNOSIS OF DISEASE.[1]

BY SHERIDAN DELÉPINE,
PROCTER PROFESSOR OF PATHOLOGY, OWENS COLLEGE, MANCHESTER.

GENTLEMEN,—Fifty years ago the notion of a "contagium vivum" as the cause of an infectious disease was considered by a great number of well-informed people to be a wild and almost absurd hypothesis. There had been, and there were still, strong advocates of the theory, but their following was small. Pasteur's work in connexion with fermentations and the features which infectious diseases and fermentations had in common revived the belief in the existence of infectious germs. In 1863 Davaine showed that splenic fever was due to the presence of a bacillus which he and Pollender had observed 13 years previously in the blood of animals which were affected with that disease. This discovery was completed in 1877 by Koch and almost at the same time by Pasteur. Koch was able to trace the whole life-history of the organism by adopting simple and accurate methods of culture. He demonstrated the production of spores, in which form the bacillus is capable of resisting unfavourable external circumstances and thus to infect certain localities more or less permanently. On his side Pasteur established with scientific rigour some of the principles upon which vaccination with attenuated cultures of the bacillus could be carried out In 1865 Villemin proved the infectiousness of tuberculosis by systematic inoculation, the results of which led him to infer the presence of a micro-organism of the same character as that found in anthrax. This inference was at length proved to have been correct by Koch, who in 1882 announced his epoch-making discovery of the tubercle bacillus which he was able to isolate and cultivate outside of the body. Meanwhile the bacterial cause of many diseases was more or less fully established in a number of cases. Obermeier in 1873 demonstrated the presence of a spirillum in relapsing fever. About 1877 Hansen announced his discovery of the bacillus lepræ and Bollinger of the actinomyces bovis. In 1879 Neisser found the gonococcus. In 1880 Eberth saw the bacillus of typhoid fever which was afterwards more fully investigated by Gaffky (1884). In 1881 Pasteur and Ogston showed the relation between various micrococci and certain septic infections or suppurations. About the same time Laveran discovered the organism of malaria in the blood. In 1883 Klebs saw the bacillus of diphtheria, which was more fully investigated by Löffler in 1884. In 1884 Koch described the cholera vibrio under the name of "comma bacillus." About the same time Nicolaier found the bacillus of tetanus. I cannot attempt to allude to all the work which has been done in recent years, but I may add to the previous list the bacillus of influenza discovered by Pfeiffer in 1890, and that of plague found simultaneously by Yersin and Kitasato in 1894.

The value of all these discoveries was not recognised very rapidly except in a few cases. This was partly the fault of methods which were not always perfect enough to make the application of the newly-acquired knowledge practical, and partly to the antagonism of very able medical men belonging to an older school. Yet, considering the very great difficulties attending the diagnosis of many obscure cases of infectious disease, one would have thought that the very precise indications given by bacteria and their products in a large proportion of those cases would have been early taken advantage of whenever possible. There are, however, several reasons why several bacteriological methods should not have found their place in ordinary work: 1. The study of practical bacteriology was not early, and is not yet generally, recognised as an *essential part of medical education*, and many medical men have not had an opportunity to convince themselves by their own observation of the accuracy of statements made by bacteriologists. 2. Although many bacteriological methods are so simple that they can be carried out with the aid of a good microscope and a few reagents, test-tubes, and flasks, there are others which are difficult to carry out elsewhere than in a laboratory where typical cultures of living organisms are stocked and animals can be inoculated, carefully isolated, and studied. 3 Bacteriological work, except in the case of simple microscopical examination, requires patient attention to details, cannot be hurried, and must be attended to at the right time; it can seldom be carried out successfully in the short and irregular intervals of a busy practice.

The extraordinary advances which surgery owes to Lister's methods, and medicine to the work of Pasteur, Koch, and their pupils, are sufficient proofs of the utility of bacteriology, and they suggest the desirability of making bacteriological methods generally available. It is not only of interest to the patient personally that the shortest methods of diagnosis should be available, but it is also a matter of public concern, for it is only by early diagnosis that effective methods of prevention and sometimes of treatment can be utilised before a disease has spread through a community or caused irreparable damage in the individual. The mastery which the sanitary authority of Glasgow has obtained over the epidemic of plague that was recently threatening that town is a good example of this.

Having since 1882 devoted much attention to the diagnosis of disease by laboratory methods, I have for many years felt convinced that such methods deserve to have a more generally recognised place by the side of ordinary clinical methods, which must of course always remain the basis of practical medicine and surgery. In addition to this, rapid, accurate diagnosis of infectious diseases is a matter of such public importance that public authorities should take an active interest in the question. When given the charge of the important laboratories at Owens College in 1891 I decided to do all in my power to bring this about. At first I met with much indifference on all sides, except in times of dramatic urgency, as when Manchester was threatened by an epidemic of Asiatic cholera in 1893. But since then matters have considerably altered, and in 1895 several public authorities had recognised the need of establishing regular connexions between their public health department and bacteriological laboratories. Some sanitary authorities in England had some time previously recognised the need of bacteriological investigation in connexion with their work; among these I may mention Bristol and St. Helens, where Dr. D. S. Davies and Dr. J. Robertson respectively had taken the matter in hand. But putting aside, as being beyond the scope of daily work, the arrangements made by the Local Government Board with Dr. Klein and other bacteriologists for special investigations, I believe that the bacteriological laboratory in Manchester was the first in this country where the bacteriological diagnosis of disease was placed freely at the disposal of all medical men in a number of districts by the combined action of sanitary and college authorities. Since that time some 60 sanitary authorities have become regularly connected with the Owens College Bacteriological Department. Our example has been followed in many other parts of the country, where, judging by the correspondence which I have had on the subject, our experiment has created much interest and has been of some use to other authorities. I do not intend here to discuss whether it is advisable for each sanitary authority to have a bacteriologist or whether, as I believe, it is better not to attempt such work except in thoroughly well-fitted bacteriological institutes having a well-paid and efficient staff, connected whenever possible with a medical school: that the work can be carried out with some success under the last conditions is, I think, proved by the growth of this work in the bacteriological laboratory at Owens College, a growth which has not been

ABSTRACT OF

An Inaugural Address

ON

SURGERY AS A SCIENCE AND AN ART.

Delivered at the Opening of the Winter Session at Queen's College, Cork, on Oct 20th, 1900

BY C YELVERTON PEARSON, M D R U I, F R C S ENG,

PROFESSOR OF SURGERY AT THE COLLEGE

[PROFESSOR PEARSON, after a few introductory remarks, proceeded to the main subject of his address—namely, Surgery regarded as a Science and an Art Though surgery could never be looked upon as an exact science such as astronomy, yet it answered the definition of a science as being a correlation of knowledge The good surgeon should be acquainted with biology, natural philosophy, chemistry, anatomy, physiology, histology, pathology, and bacteriology To these must be added at least an elementary knowledge of logic The foundation stone of surgery, however, was anatomy and anatomy learned by careful dissections Professor Pearson then went on to speak of the relative importance of the other sciences Morbid anatomy was of course of special importance Chemistry was necessary for the true understanding of much of physiology, and physiology could not have advanced so far as it has without the help of biology Professor Pearson continued]

PATHOLOGY AND MORBID ANATOMY

Last but by no means least let me refer to the science of pathology or the study of diseased conditions and processes which strictly speaking, bears the same relation to morbid anatomy that physiology does to normal anatomy, but so closely are the two connected that while pathology could never have existed without physiology, the latter, on the other hand, owes very many of its most important advances to the former Now it is evident that in order that we may become scientific surgeons we must closely study the appearances presented by disease both in the living and the dead body, so that we may be able to recognise and to deal with them in practice Further, we must be able to understand the nature of diseased processes and the means designed for resistance to invasion the provisions made for natural recovery, and the phenomena of natural and acquired immunity from certain diseases—in a word, the marvellous *vis medicatrix naturæ*—if we are successfully to guide our patients through the tempest of disease to that blissful haven which is known as health

It is in the possession of such knowledge that the truly skilful and scientific surgeon or physician excels his more empirical brother by frequently watching and guiding the natural processes of recovery rather than—as is so frequently done—interfering with them by the indiscriminate use of drugs Now how is such knowledge as this to be obtained? So far as the study of diseased conditions in the living is concerned you are provided with ample material in our clinical hospitals where, if you only give the amount of time and attention that is desirable in bedside observations, it will be your own faults if you do not gain a very thorough acquaintance with all the ordinary diseases that flesh is heir to On the other hand, it is with deep regret that I feel obliged to admit that our opportunities for the study of morbid anatomy and pathology are not all that is desirable This is in part due to the natural prejudice, amounting almost to a superstition that exists in this country against the performance of post mortem examinations In my opinion it would be much better for the whole community at large if this state of things were
death where the obedie
of "Death from heart
medical evidence—would a carefully conducted post-mortem examination reveal a totally different explanation of the real cause of death Moreover, I have long been fully persuaded in my own mind that the extremely careless way in which burials are permitted in Ireland, previously to registration, and often without proper certification, is a practice strongly to be deprecated and is calculated to prove a direct incitement to crime It is certainly about time that the authorities awoke to their proper sense of duty in this respect Notwithstanding these difficulties the industrious student, by making use of those opportunities presented to him, may do a great deal, such as losing no chance of witnessing a post mortem examination when it occurs, by the careful study of recent and preserved pathological specimens, and more especially by utilising his powers of observation in the dissecting room where he will find a mine of wealth At a time when pathology as a distinct course was not included in the curriculum, by carefully taking advantage of the opportunities presented to me in the dissecting room in the years during which I acted as demonstrator I gained a knowledge of pathology which has proved to me of inestimable advantage in dealing with disease

There is, however, another aspect in which I wish to review this question, and that is the condition in which this and the sister colleges have been obliged to remain with regard to the teaching of pathology It certainly would be an unpardonable evasion of duty on my part if I did not protest in the strongest manner against the neglect to which we have been subjected in this respect And it certainly does not redound to the credit of successive Governments that at a time when pathology has made such enormous strides by leaps and bounds, when its importance in relation to the prevention and treatment of disease has been recognised in all civilised countries throughout the globe when men of the highest scientific attainments are to be found devoting their lives and in many instances their private means, nay, in some cases even their own persons to pathological investigations in the cause of suffering humanity, it should be left to the respective governing bodies of the Queen's Colleges in Ireland to provide a teacher in pathology for their medical schools in order that they may not be behindhand and it speaks volumes for the disinterestedness of the medical profession when men of recognised ability and careful training have been found to come forward to fill a gap that should never have been allowed to exist for a remuneration that is wholly inadequate I need scarcely say that in the natural course of events it is not to be expected that such men will remain with us unless they are at least provided with a salary that will enable them to devote their entire time to the study and teaching of pathology May I express the sincere hope that the Government just returned to power will recognise the justice of our claims and inaugurate the dawn of a new century by a substantial recognition of our grievances As you well know I am no politician, and even if I were it would not be within my province to touch on political matters, but the subject on which I am speaking is not a political one and I feel that I am speaking nothing but the simple truth when I say that I regard the manner in which the subject of pathology has been permitted to remain unendowed in our school at the close of the nineteenth century as nothing less than a national disgrace If any efforts on my part either by words or actions, may prove of some slight assistance in bringing this most important matter under the due notice and recognition of Her Majesty's advisers the knowledge of having done my duty will be ample reward

Apart from its importance in relation to medical and surgical teaching, consider the advantage to the public in general of having at hand a skilled pathologist provided with a fully-equipped laboratory to whom to refer such important questions as the investigation of doubtful cases of rabies and the bacteriological examination of milk and water; and at the present moment, when the possibility of a visitation of the much dreaded plague is not altogether a remote contingency, to whom would the medical officer of health refer the investigation of doubtful cases if not to one who devoted his entire time to pathological research?

---

[1] Bearing on typhoid fever diphtheria, tuberculosis botulism, cholera plague, various animal diseases, milk supplies water supplies disinfection &c

Having referred in a very superficial manner to the importance of studying each of the foregoing sciences I may point out that in many instances it is requisite for us to employ most, if not all, of them for the thorough investigation of a single problem in surgical science. We are told that "animated, or rather inspired, by a far more comprehensive spirit of inquiry than that which relates to the human species alone, John Hunter's view of pathology was an extension of a colossal physiology and a corresponding anatomy embracing the whole living creation. It was from this vast range of biological science that Hunter sought to interpret the structural condition and the phenomena of life in any one species; and thus, for example, to enlighten our otherwise isolated knowledge of human anatomy, physiology, and pathology; of man, structurally and functionally, in the states of health and disease. From this elevated point of view we must look to appreciate justly the Hunterian conception and its influence on the British school of surgery. Subsequently, it became apparent how largely and intimately the sciences of physics and chemistry enter into this system of biology; and thence we might trace the grand contributions of the continental schools more especially, and particularly in Germany and France. Here, then, we discern the three primary elements of modern scientific medicine."

Now let us see what is the aim and object of all this scientific knowledge? To you who mean hereafter to be thoroughly practical surgeons and physicians the two important considerations are first to be able to recognise and diagnose disease, and second to be able to treat it with success. Now at one time it was thought that the surgeon's duty in the matter of diagnosis was a very much simpler matter than that of the physician and, consequently the highly skilled and cultivated physician was looked upon as occupying a more elevated position than the surgeon I have not the slightest inclination to institute a comparison between the two—each is worthy of the highest regard. But it is my duty to point out to you that the modern surgeon requires, not alone all the means and knowledge possessed by the physician, but even more in those cases where a diagnosis can only be arrived at by the employment of surgical instruments and appliances, which cases are so numerous that it is unnecessary for me to specify any of them. To be a good diagnostician you require then the fullest development and training of all your senses; while it is important to learn the history and nature of the symptoms from the patient, it is still more important to make your own observations. He who depends chiefly or altogether on the details of symptoms will make more mistakes than one who places most reliance on his own powers of observation and physical examination. Take, for instance, the amount that is conveyed to the mind of the skilled observer by one look at the patient. Then in the application of touch in its highest state of development what an amount of information is conveyed—the sensations of true and false crepitus, of fluctuation, of elasticity, of resistance, of mobility, and so on. We have need of our hearing powers in the application of percussion and auscultation to the diagnosis of abdominal tumours and various other conditions. For the employment of smell and less frequently of taste I could adduce several examples where the use of these senses furnish much assistance. But I pass to the brief consideration of some of those applications of scientific methods which are of more recent growth; amongst which we find the larger number are derived from the science of physics, such as the use of the clinical thermometer, which not alone conveys to us when suitably employed the knowledge of the general bodily temperature, but by a series of consecutive observations the results of which when transferred to a chart will often in itself enable us to arrive at a correct diagnosis and is of such invaluable assistance in conveying at one glance the progress of the case. What a contrast in this respect our surgical wards present to-day with what they did some 25 years ago, when a temperature chart was rarely seen and when the surgeon relied on that most deceptive sensation of temperature derived from contact of his own hand with the patient's body. Of less frequent employment and more restricted use is the surface thermometer, by which local variations of temperature can be determined.

Then by the application of acoustics in the use of the stethoscope or its numerous modifications the surgeon often derives information not otherwise obtainable. As another example of the value of acoustics let me cite the use of the tuning-fork in certain affections of the ear.

From optics we gain still more extended advantages—e.g., the use of the ophthalmoscope, the laryngoscope, the rhinoscope, &c. And when combined with the electric light we have the cystoscope, with which we can illuminate and examine the interior of the bladder, and thus recognise certain diseased conditions in the living in a manner undreamt of by our forefathers. Another optical instrument, the value of which to the diagnostician cannot easily be over-rated, is the microscope. I cannot in this short sketch convey to you the numerous instances in which it has to be employed, but may especially remark on its assistance in diagnosis of affections of the urinary organs, the determination of the character and structure of various tumours, and the examination of the blood in certain obscure conditions where, by counting the corpuscles and determining the presence of leucocytosis, the existence of suppuration, &c., may be inferred. It is scarcely necessary to refer to its association with the discovery and advancement of pathological science, called bacteriology; but I take this opportunity of remarking that owing to the rapidly advancing nature and highly specialised character of the latter science there is a growing tendency amongst medical men to refer most, if not all, of their microscopical examinations to the pathologist. I think this tendency, if allowed to progress too far, will prove most disastrous. For what purpose do you learn the use of the microscope in connexion with practical biology, chemistry, histology, and pathology if, when it comes to be a question of diagnosis, you are going to hand over to another in all cases that portion of the examination which, owing to your education you ought to be fully competent to conduct yourself? There is no doubt that those who have their time completely occupied with the various other duties of the profession are obliged to resort to this assistance, and it is equally important that we should all seek the assistance of an expert in pathology in certain important and difficult instances; but, believe me, he will make the more highly accomplished physician or surgeon who is able to rely on his own powers of observation.

[After a reference to the use of the x rays and to the value of a knowledge of chemistry in surgery Professor Pearson pointed out how essential it was in investigating a case to make use of all the means of search at our disposal. He then passed on to consider the germ theory of disease and gave a short life-history of the theory, concluding with an account of the technique of an operation carried out with all the modern precautions as to asepsis. He then proceeded to the consideration of the second part of his subject:]

SURGERY AS AN ART.

Let me now pass for a few moments to the consideration of surgery as an art. If we seek for a definition of art in its most extended and popular sense we find that it means everything which we distinguish from nature. The term is, however, usually employed in a more restricted manner and various definitions are given according to the particular standpoint from which the subject is viewed. Thus Schiller tells us: "Art is the right hand of Nature; the latter has only given us being, the former has made us men"; while Lavater says: "Art is nothing but the highest sagacity and exertion of human nature, and what nature will he honour if he honours not the human?" We are told that surgery was already an art when medicine proper was but a phase of superstition. The earliest notices of it occur among the Egyptians who, as we find represented on obelisk and in the temple, practised incisions, scarifications, probably even amputations, long before the date of the Ebers papyrus 3500 B.C. An operation for cataract was also known to them. The surgery of the Jews was an importation from the Egyptians. Surgery was held in very high esteem in very remote times among those who practised the Indian healing art, who had a proverb to the effect that "a physician who is no surgeon is like a bird with but one wing." They had a large assortment of steel cutting and cauterising instruments and held that "what drugs and knives cannot cure may be cured with fire" In some of our museums may be seen surgical instruments contemporary with the votive offerings of the remot [illegible]

However interesting it might prove to trace the history and development of the surgical art I have no intention of so occupying your time, but I would refer you to historical records and a modern work by the late Mr. J. F. South, entitled, "Memorials of the Craft of Surgery in England."

We are concerned with the present, and permit me to tell you that in order to become successful surgeons it is quite as necessary for you to study the *art* as well as the *science* of surgery. A truly great surgeon should perform all his work in a really artistic manner; a little experience will soon convince you that the cleanness with which an incision is made and the accuracy with which the margins are subsequently co-apted have an influence on the rapidity of union and on the subsequent appearance of the scar that is quite apart from the details of the most perfect asepsis. This comes to be a matter of the gravest consideration to the patient when we are dealing with operations on the face or neck and the subsequent appearance of the scar is a matter which will make or mar the reputation of the surgeon.

Now it is of some importance that we should consider what steps are taken to secure to the student of surgery the development of this artistic skill. Well, in a somewhat indefinite way they may be considered as amply sufficient, provided that the student avails himself of all the opportunities presented to him, and of these there is, first of all, dissection. It is by the careful and continued use of the scalpel and forceps in the dissecting-room that the hands of those not previously accustomed to such work become trained to some extent. Then the most excellent opportunities are presented in the work carried on in our biological, our histological, and pathological laboratories for acquiring the art of accomplishing the most delicate manipulations. When engaged in these operations take my advice and accustom yourselves at the earliest opportunity in the use of both hands [illegible] d to infer that the art of [illegible] ophthalmic [illegible] is scarcely [illegible] the inter- [illegible] of advantage, whether it [illegible] scissors or in the removal of a pair of forceps. What an awkward appearance is presented by the efforts—often of a fruitless character—of an unskilled assistant in attempting to release a pair of compression forceps with the left hand.

Again, you have a further opportunity of learning the use of cutting and other instruments when taking out the course of operative surgery. I have heard a very eminent surgeon, for whose opinion on most surgical matters I entertain the deepest respect, express the opinion that operative surgery was a branch of the usual surgical examination to which he attached comparatively little importance; with this opinion I desire to join issue. Is it to be expected that anyone will be competent to operate on the living body who is not able to do so on the cadaver? Are his patients hereafter to be the subjects on whom he is to practise to acquire manipulative skill? If the examination in surgery was simply required for the purpose of permitting the candidate to acquire a qualification in medicine I should have no objections to offer, but so long as our universities and colleges grant degrees and diplomas in surgery in my opinion they should be satisfied that their graduates and licentiates are skilled in the use of surgical instruments and appliances.

An additional opportunity is presented in our hospital work for attaining manual skill to those who take advantage of such training in the application of bandages, splints, and dressings, and how easy it is to detect the 'prentice hand in the application of a simple bandage by first giving him a choice of limbs and then asking him to bandage the opposite one. Here the man who has only practised bandaging on one side of the body at once comes to grief. Now from these considerations it may be fairly inferred that if any intelligent student does not become a fair artist as well as a scientist in his profession the fault lies with himself. Notwithstanding this I hold the opinion that the training in the practical, and more particularly the manipulative, portion of our profession leaves much to be desired, and I do not know of any form of training that would prove of so much

[illegible] were considered excellent surgeons make such a display when sawing through a bone in an ordinary amputation that it was evident to any observer that they had never learned to saw a bit of wood, with the inevitable accompaniment of locking of the saw and splintering the bone, and on other occasions the most clumsy attempts made at the introduction of certain forms of suture that were a little bit out of the common.

Now I am not suggesting that a course of carpentry or sewing should be added to the burdens of what appears to be an already overloaded curriculum, but lucky is the man who has been taught the use of the needle in childhood, best of all when it has been done at his mother's knee. Those of you who have not had such advantages, or who having had the opportunities did not profit by them, will do well while you are yet young, and while your fingers are yet pliable, to practise for yourselves the application of all the forms of suture on some simple fabric before you attempt the application of a needle and silk to the intestines of a human being. Learn to use a saw and a chisel on a piece of wood before trying them on a living bone.

What is the present position of surgery as an art? In an edition of his classical work on surgery, written several years ago, Mr Erichsen expresses himself in the following terms: "To my mind it appears as if we had already reached something like finality in the mere manipulative art of surgery; though I hesitate much to use the word 'finality,' for I know well how apt a man is to suppose that art, to the prosecution of which he has devoted his life, to have attained to the fi[illegible] at the question as [illegible] not but come to the conclusion that we can scarcely hope to pass far beyond the line at which we have arrived in the direction of extreme precision and almost absolute certainty in the mechanical performance of the operations of surgery, and that in this direction the progress of modern surgery is nearly barred. At the same time we may reasonably expect that the details of [illegible] from time to time [illegible] skill of individual [illegible] mechanicians, or [illegible] as aids to our art [illegible] indeed, have been the advances, of which I [illegible] to the great improvements that have taken place in dealing with the abdominal viscera, such as the introduction of Senn's plates, of decalcified bone-bobbins and Murphy's buttons, and the more perfect methods of suture for either lateral or end-to-end anastomosis of the intestines; the improved methods of dealing by operative procedure with certain forms of fracture; and the introduction of serum therapeutics, which is, of course, the outcome of pathological and bacteriological research, but which promises much and has already proved of inestimable value in to a large extent minimising the severity of that much-dreaded disease diphtheria.

I must pass on to another matter. The large majority of those who go out into the world as physicians and surgeons become what is known as general practitioners, and it should therefore be your ambition to become acquainted with all the branches of your profession, otherwise you will never be sound advisers. To the few it is permitted to select some particular branch and become what is known as specialists; where the opportunity offers the temptation to do so is very great, as it largely diminishes the responsibility of the individual and makes his work easier and more agreeable, but has an undoubted tendency, on the other hand, to narrow the mind and obscure the discriminating powers. I well know that in treating of specialists and specialism I am treading on delicate ground, but I believe the rapidly growing craze of the public for specialists is fraught with the gravest danger to themselves and to those who pander to it. Not so long ago I was asked to give the name of someone whom I could recommend as a liver specialist. My answer was that the profession did not recognise the existence of such a person and that anyone who posed as such could be little better than a charlatan; that anyone who was competent to treat affections of the liver should be equally competent to deal with affections of the heart and lungs and of the stomach and kidneys &c. Such is the teaching that we must necessarily derive from the study of physiology. Any one student of standing knows that you cannot alter the functions of any one important

Prognosis.—Without complications and in an otherwise healthy individual the prognosis is good.

Treatment.—During the rise, antipyretics and if necessary cold applications and aperients; during the remission, quinine and some saline diaphoretic mixture; and after the attack, tonics. If the temperature is over 104° 10 grains of phenacetin with or without five grains of calomel and a hot lime drink are commonly given. Cold applications are necessary if the temperature refuses to react to drugs; as ice is difficult to obtain on the Gold Coast it is usual to resort to a brine bath—i e., salt, vinegar, lime-juice, and Florida water are mixed with the water and the patient is either sponged with this, packed, or placed in the bath. The latter is at times dangerous owing to the shock which it produces. The saline diaphoretic mixture generally used is liquor ammoniæ acetatis in one-drachm doses, together with spiritus ammoniæ aromaticus, spiritus ætheris nitrosus, and a little syrup of orange. Quinine is often given in 10-grain or 15 grain doses twice a day, in the morning and in the afternoon. This, of course, is only given in the remission of the fever, and as soon as convalescence is established it is cut down to 10 grains once a day; then five grains once a day, next five grains every other day, and lastly, it is stopped after a little time. In the convalescence stage quinine is only given in the morning. In convalescence, in order to treat the anæmia and to improve the general system of the patient some tonic is necessary. A common prescription here is 10 grains of the citrate of iron and quinine with three minims of the liquor of strychnine hydrochlorate and a little syrup of orange for a dose. After repeated attacks of fever and the consequent anæmia a patient is invalided to either (1) the Government Sanatorium at Aburi, situate on the hills 26 miles from Accra at an elevation of 1440 feet and surrounded by beautiful gardens; or (2) a sea trip to Sierra Leone, Canary, or England according to his condition.

Prevention.—This is important and much can be done by using common-sense and obeying the ordinary rules of life and hygiene. Chills must be avoided and clothes should be changed if they get wet (this, however, is often impossible). Constipation and excesses can be avoided. Proper and sufficient food should be taken if it can be procured. Recreation and certain kinds of amusement can easily be obtained on the coast and often help to counteract mental worry. Possibly some alcohol should be taken to counterbalance the deleterious effects of a hot moist climate. If possible, Europeans should live in the good airy bungalows which are common on the coast and which have been built by the Government for officials, and should also be provided with mosquito nets, which I am glad to say are in general use A little quinine in the damp cold weather or when wet or before a long trying march has been found useful In my opinion persons have many times been prevented from having an attack of fever by being given a purgative and a few grains of quinine. As the country gets opened and as the forests are cut down and the swamps are drained by the gold-mining and other industries now beginning, the malarial fevers will, in my opinion, diminish, even as they have in the Fens and in Kent

Accra.

ON THE DIAGNOSIS OF THORACIC ANEURYSM BY THE ROENTGEN RAYS.

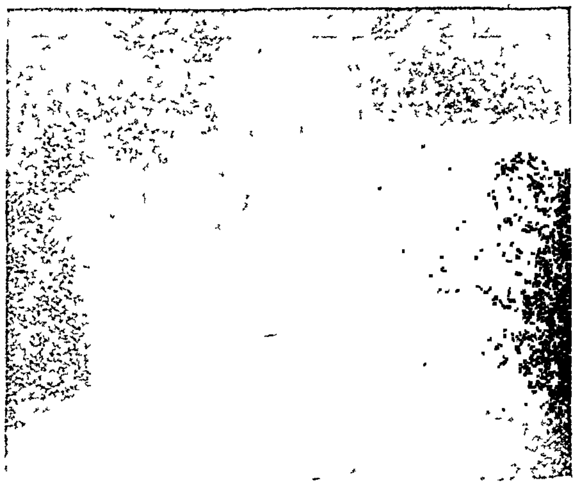
By HUGH WALSHAM, M.A., M.D CANTAB., M R C.P. LOND.,

ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST; ASSISTANT MEDICAL OFFICER IN THE ELECTRICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

MANY aneurysms of the aortic arch can, of course, be readily diagnosed without any help from skiagraphy, but there are others, and they are not a few, in which the physical signs leave us in doubt between an aneurysm of the aorta and a mediastinal new growth, or the aneurysm may be unsuspected In cases such as these the x rays come to our aid and I would emphasise the importance of examining such a case with the screen, because the pulsation of an aneurysmal sac can only be discovered in this way in an aneurysm buried deeply in the thorax. The following two cases, both of which came under my observation in the out-patient room at the City of London Hospital for Diseases of the Chest, are, I think, worthy of record.

CASE 1.—A man, aged 33 years, came to the out-patient room on April 19th, 1899. He gave the following history. He had had syphilis 16 or 17 years ago. 12 years ago his right elbow-joint was excised by Lord Lister in King's College Hospital. Five or six weeks before coming to the hospital he noticed a "cramp-like feeling" in the region of his heart which extended down his left arm. This sensation only lasted for a few minutes at a time but was severe. This lasted for two or three days and then disappeared. About the same time he noticed that he was getting short of breath on exertion. For a few weeks he had had a slight cough with frothy expectoration. He had never had rheumatism. On examination the heart's impulse was found to be in the fifth interspace in the left nipple line. In the third and fourth interspaces on the left side, three and a half inches from the mid-sternal line, there was a diffuse area of expansile pulsation over which a systolic murmur was audible. The aortic and pulmonary second sounds were clear. At the apex there was a systolic murmur following the first sound. The expansion of the left side of the chest was a little less than the right. The breath sounds all over the left side of the chest were a little weak. There were numerous crepitations to be heard over the left base behind. The pupils were equal and reacted to light. Both vocal cords moved well. The pulse was 72, regular and equal on each side. On May 3rd, 1899, he was admitted to the hospital under the care of Dr. Eustace Smith. The first skiagram (Fig. 1) was taken the day before his admission.

FIG. 1.



Showing the shadow of the aneurysm at the left base of the heart.

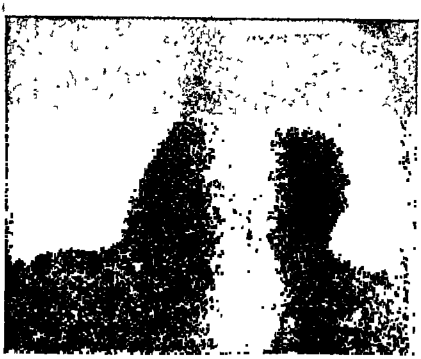
The chest is viewed from the back. The first point noticed is the very peculiar shape of the heart. The projecting shadow to the left of the base of the organ corresponded exactly to the pulsation felt on the chest wall. The shadow occupies the position of the left auricle. On a screen examination well-marked pulsation was visible in this projecting shadow. The diagnosis arrived at was that the patient had an aneurysm, and if aneurysms of the left auricle were not so extremely rare, there being, according to Dr. Wickham Legg,[1] only three or four cases on record, it might have been thought from the skiagram that the patient had an aneurysm of this chamber of the heart. The patient left the hospital of his own accord on June 1st, 1899, the physical signs remaining practically the same. A fortnight after, owing to palpitation of the heart, he went to the Middlesex Hospital and was admitted, remaining there for three weeks. After his discharge from the hospital he kept fairly well for five or six weeks. He attended again at the Middlesex Hospital for examination and was again admitted for six weeks. His condition remained much the same until the last week in November, 1899, when he fainted in the street.

---

[1] Dr. Wickham Legg: Some Account of Cardiac Aneurysms, Bradshawe Lecture, delivered before the Royal College of Physicians of London, 1883.

After this he came again to the City of London Hospital for Diseases of [illegible] itted to the hosp [illegible] On examination the physical [illegible] same as before but with the additio [illegible] base of the heart. He informed [illegible] of the physician under whose ca [illegible] in the Middlesex Hospital was that he had an adherent pericardium. He was discharged on Jan. 18th, 1900. On April 7th, 1900, he came again to the out-patient room complaining that for the last few weeks his shortness of breath had increased. On April 12th, 1900, the second skiagram (Fig. 2) was taken, the interval between the two skiagrams being almost exactly 12 months. The chest is viewed from the front. It will be at once seen that the shadow of the tumour at the left base of the heart has increased to more than double its original size. It also shows evidence of commencing dilatation of the right side of the heart. On a screen examination the pulsation in the sac was very distinct. I think the second skiagram leaves no doubt about the aneurysmal nature of the tu[illegible] rvation.

FIG. 2.



The second [illegible] from a diagnostic and [illegible]

CASE 2.—A man, aged 42 years, came to the out-patient room on Nov. 29th, 1899. He gave the following history. He had never had any previous illness, being quite well up to 18 months ago when he began to suffer with shortness of breath on exertion which had gradually increased. He had had pain extending down the right arm. He also noticed that the veins on the right side of his neck were swollen. He had had a cough with slight expectoration but no hæmoptysis for 12 months. For the last two months he had been wasting rapidly, having lost nearly two stones in weight. Nine months ago he said that his face and neck were swollen but this swelling had now disappeared. On examination the superficial veins over the upper part of the right side of the chest and in the epigastric region were full and tortuous There was no pulsation anywhere to be discovered. There was dulness to percussion with tracheal breathing all over the right side of the chest in front—the dulness extending a little to the left side at the level of the second costal cartilage. The dulness was also marked at the back of the chest on the right side but not so absolute The breath sounds over the left chest were normal. The heart's impulse was displaced downwards and outwards in the sixth interspace just outside the left nipple line. There was a soft systolic murmur following the first sound. The murmur was conducted towards the axilla. The pulse was weak, soft, and regular, and appeared a little weaker in the right radial artery. I was in doubt between an aneurysm and a new growth The patient was admitted to the hospital on Dec 13th, 1899, under the care of Dr. Eustace Smith The first skiagram (Fig 3) was taken on Dec. 7th, 1899. The chest is viewed from the front. It is at once seen that there is a large tumour occupying the right side of the chest and extending upwards nearly to the right clavicle and downwards to where it meets the shadow of the liver. It also extends a little to the left of the sternum at the level of the second costal cartilage on the left side. It seemed hardly possible that an aneurysmal sac could reach such enormous dimensions. I was therefore—taking into consideration the rapid wasting—in favour of a mediastinal new growth. The patient remained in the hospital until March 15th, 1900, and was discharged decidedly improved. He returned to the hospital the following month saying that although his breath was less short his cough had increased. On examination the physical signs were the same with the addition of rhonchi over both bases. The bronchial catarrh soon cleared up under treatment. Until June, 1900, the patient attended at the hospital once a month to report himself. The second skiagram was taken on April 26th, 1900, the interval between the two being very nearly five months On comparing skiagram 4 (see Fig 4) with skiagram 3 it will be seen that the mass on the right side of the chest has undergone a certain amount of contraction, its shape being quite altered. This contraction of the tumour leaves now, I think, no doubt about its aneurysmal nature.

FIG. 3.

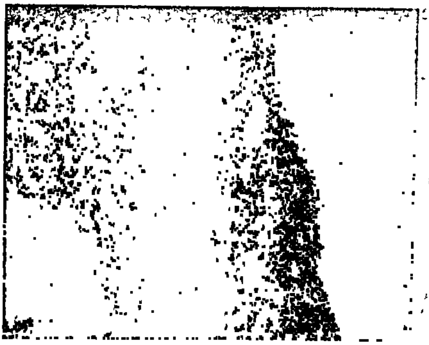


FIG. 4.

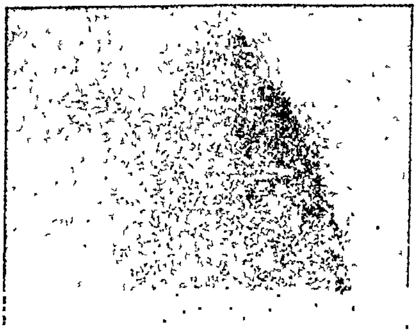


The shadow has now much contracted.

Since the above was written I have discovered an aneurysm of the descending thoracic aorta in a patient, by means of the Roentgen rays, which was unsuspected, the patient having been under treatment for intercostal neuralgia.

Harley-street, W.

UNIVERSITY COLLEGE OF NORTH WALES.—The half-yearly meeting of the court of governors of the University College of North Wales was held at Rhyl on Oct. 24th. Lord Kenyon was elected President in succession to Mr W. Rathbone, who retired after 15 years' service. The financial report showed a deficit of £1604.

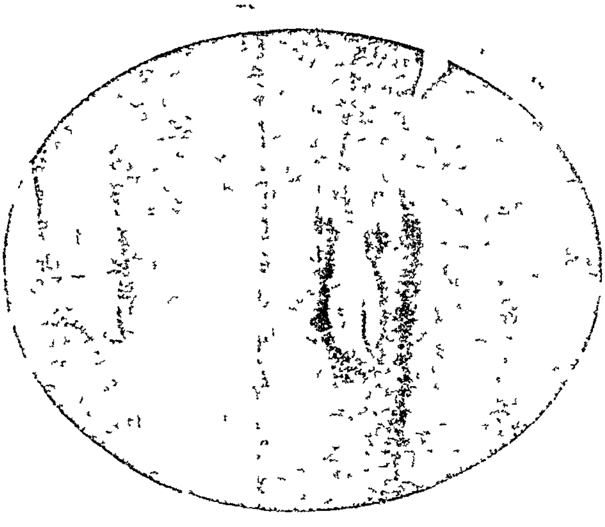
HAVE MATERNAL IMPRESSIONS ANY EFFECT ON THE FŒTUS IN UTERO?

BY WILLIAM DUNCAN, M.D. BRUX., F.R.C.S. ENG.,
OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL.

NOWADAYS it is the custom to scoff at the idea that maternal impressions during pregnancy can injuriously affect the unborn fœtus and when cases in support of the theory are recorded they are usually described as mere coincidences. Those who deny the influence of maternal impressions say (1) that deformities are rare but maternal impressions are common; (2) that deformities occur where there is no history of any maternal impression; and (3) that as there is no nerve-tissue in the umbilical cord no impression can be carried from the mother to the child. On the other hand, the belief in the power of maternal impressions to cause deformities in the fœtus in utero was pretty general in the medical profession up to the beginning of the last century; and even at the present day there are not a few medical men—myself amongst the number—who are unable in the face of many well-authenticated cases to refuse to believe that maternal impressions and fœtal deformities do sometimes stand in the relation of "cause and effect," even though it be impossible to say definitely what the *modus operandi* is. The case which I am about to relate is so extraordinary that I feel it due to the profession to publish it.

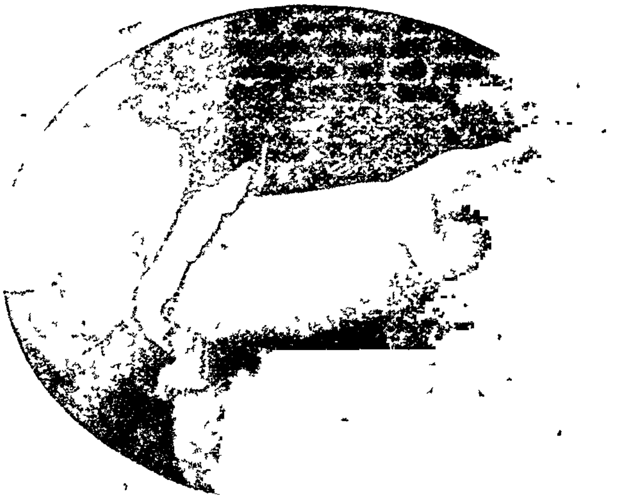
The wife of a medical man consulted me in 1898 for dysmenorrhœa and sterility. Finding an acutely anteflexed uterus I dilated the cervical canal, with the result that soon afterwards she became pregnant. When she was seven weeks pregnant her husband took her to the seaside and whilst there they were photographed together. (See Fig. 1.)

FIG. 1.



When the wife saw the photograph she exclaimed that her husband's "right hand looked deformed as if it had only a thumb and little finger." On frequent subsequent occasions she showed the photograph to friends, always pointing out the deformity to them When the child was born—after a normal labour—the *right* hand was deformed as seen in Fig. 2, and the resemblance to the father's *right* hand, in comparing the two photographs, is sufficiently striking. Now comes a very remarkable occurrence. The nurse in charge of the baby whilst out walking one day showed the deformed limb to a neighbour who happened to be a few weeks pregnant. She was very shocked, but remarked, "What a lucky thing that both arms are not deformed." This woman was duly delivered of her first child at full term, and "*both its hands and feet were deformed.*" The mother was of a very nervous temperament. She often expressed her opinion that it was the shock of seeing the hand of my patient's child that caused her child to be born deformed. She would allow no one to see the child, although my patient's husband tried hard to get permission to have it photographed. She has since been removed to an asylum. Both of the children, apart from the deformity, are well developed and healthy. No previous cases of deformity can be ascertained as having occurred in either family.

FIG. 2.



In his presidential address to the Glasgow Obstetrical Society on Nov. 25th, 1891, Dr. George Halket[1] ably reviewed the whole subject of "infantile deformities and maternal impressions and emotions." He mentioned several recorded cases, three of which, as they are somewhat similar to that which I have just recorded, I may briefly quote.

In the first case an infant was born alive with the index and middle fingers wanting from one of the hands. The mother was a young woman who knew nothing of maternal impressions, but when she was told of the deformity of her infant she stated without hesitation that she had to work for some months after her marriage under a foreman who had lost two fingers through an accident; that the first time she saw his hand she had a shivering fit; and that every time she saw him she could not keep from thinking of his deformed hand. In the second case a patient in her first pregnancy was served daily with milk by a boy who had lost his middle finger, and as he handed her the milk she always noticed the absence of that finger. When her child was born the middle finger of one of the hands was wanting. In the third case a medical man narrated to a female friend who was in the early months of pregnancy, how one day a man was brought into his surgery with the right hand completely cut off by machinery. It made a marked impression on the lady who related the incident several times to friends. When her child was born it had only one hand.

Surely these cases show indisputably that maternal impressions have some effect in producing infantile deformity; and although the action cannot be explained pathologically I may end by saying (as Dr. Halket does): "There are more things in heaven and earth than are dreamt of in our philosophy."

Harley-street, W

TONITE EXPLOSION AS A CAUSE OF DEATH.

BY A S. MORTON, M.D. DURH.

ON August 18th, 1900, at 10.40 A.M., I was requested to go immediately to a man who was said to have been severely injured by some explosive. I went at once and on my reaching the spot I found that the man was already dead. The coroner for Ipswich ordered a preliminary inquiry at 4 45 P.M. on the same day, requesting me to give evidence but not allowing any post-mortem examination on that day.

---

[1] Glasgow Medical Journal, January, 1892.

I then gave the following evidence. The body was that of a man, about 37 years of age. He was fully dressed, his clothes were torn in places, and there was a large wound in the left thorax. I then stated that to the best of my belief death was caused by hæmorrhage and shock due to a wound of some internal organ by some explosive or other and that a probe passed into the body for its entire length in the direction of the heart, but whether that organ was wounded or not I could not say without a post-mortem examination. The jury requested a necropsy to be made, and this was done by order of the coroner on Sunday morning, August 19th, at 10 A.M. It was most carefully carried out by myself, together with the able assistance of Dr. A. W. Paterson of Ipswich, and in the presence of Mr. S. O. Eades. The clothes had been previously removed. There were a number of wounds of a more or less severe nature all over the front and side of the left half of the body. The right side had almost entirely escaped, as also had the head and face. There were a number of pieces of metal, varying in size from that of a shot-corn to about an inch in length, extracted from some of the wounds. The chief wounds were one which passed immediately below the seventh rib in a line with the axilla, allowing the insertion of the forefinger, and from which a piece of omentum was protruding; another hole was just above the middle of the left pubes from which gas was issuing, showing peritoneal perforation; there was a wound over the left deltoid at the top of the shoulder of about the size of a shilling; another wound about three inches long over the centre of the left biceps; also a wound about as large as the palm of the hand in front of the left upper forearm and corresponding to the area embraced by the median cephalic and basilic veins; the metacarpo-phalangeal articulation of the left thumb was torn open without fracture; and a piece of metal had perforated the left boot at the outer side and close to the toe-cap. This piece of metal had fractured the middle toe as well as injuring the big toe and the second toe. All the wounds of the outer surface of the body were peculiar in this respect, that the soft tissues were completely blown away—they looked as if eaten away by some animal. There was no blackening or discolouration of the surrounding skin, nor was there any smell of fire or of gunpowder, the skin looking perfectly clean and normal. The heart was normal and uninjured. The brain, the kidneys, and the spleen were all healthy and not damaged. The lower lobe of the left lung was perforated. This wound was a continuation of the wound under the seventh rib; it then passed through the diaphragm, then along the anterior superior surface of the stomach, which it perforated, and it also passed through the left lobe of the liver. The intestines did not appear to be injured. The clothes which the man had worn were full of holes; there was no smell of fire upon them nor was there any discolouration. The buckle of the left brace was broken and the broken portion was found in the body. Some of the blue material of a cloth coat was found, still undiscoloured, partly buried in the horn handle of a pocket knife.

It came out at the adjourned inquest on August 24th, that the Ipswich Regatta had been held on August 17th, when some fireworks and distress signals were exploded in the evening. It is supposed that one of the latter did not explode from some cause or other and that it fell upon the area of a timber-yard, where it was found on the following day and was examined by various workmen. How it exploded is still somewhat mysterious—that is to say, whether by percussion, by friction, by striking upon a cartwheel, by the application of a match, or by the production of a spark by means of a stone—as all of these methods were attested to by various witnesses. Captain M. B. Lloyd, H.M. Inspector of Explosives, who gave his evidence, stated that "the nature of the explosive which caused the deceased's death was what is known as a socket distress signal or a socket-sound signal. It was evidently, however, a defective one. Faulty manufacture, and many other things, would cause a signal not to explode. The inspector then went on to explain by means of a sectional dummy signal the exact nature, composition, and properties of it To all intents and purposes it was a shell and was similar to those that were recently used in the artillery except that its envelope was not of so substantial a character. The flash of the discharge lighted a time fuse which burnt for five or seven seconds and then ignited a charge of tonite, a very powerful explosive, making a report equal to a 15 or 20 pounder gun. The charge was sufficient to blast out rock to the depth of a yard."[1]

Some important questions were propounded at the inquest: "What is a firework?" "Was he a left-handed man?" (This was shown to be the case.) "Was his death due to the explosion or did someone else shoot him?" since shot was discovered by me in the body *before* the post-mortem examination. It came out subsequently that he had been shot some time previously in the same side and several shot-corns were extracted at the time of this injury. He had extensive adhesions of old left pleurisy and this prevented the complete collapse of the lung when perforated by the tonite explosion. "Was he able to walk a few—three or four—yards, and say good-bye to one or two of his old friends after so severe and mortal an injury?" The evidence of two or three of the witnesses proved that he was able to do so. "Could he have so walked and spoken without the old adhesions of his left lung, which prevented instantaneous collapse?"

Putney, S.W.

ARRESTED MENTAL DEVELOPMENT FOLLOWING DEPRESSED FRACTURE OF THE SKULL; TREPHINING; IMPROVEMENT.

By ALFRED CLARK, F.R.C.S. Edin.

ON July 10th, 1900, I was consulted in reference to a girl, aged 11 years, who had been for three years in an asylum because of "idiocy," accompanied by boisterous behaviour, which rendered her quite unmanageable at home. The patient, a tall and well-developed mulatto, who walked with a shambling gait, was brought into my consulting-room and demonstrated her high spirits by repeatedly pushing her mother off her chair, punching her on the chest and back, and pulling her hair, all with perfect good humour. She called me by her father's surname and evinced a strong desire to pull my chair from under me, for which reason my physical examination was limited and expeditious. I found a depression of the skull in the left occipital bone near the parieto-occipital suture and about two fingers' breadth from the middle line. It was about one and a half inches long and three-quarters of an inch wide. I had a fleeting view of the optic discs, which were normal, as were also the pupils.

The history of the case was that the child was bright and intelligent until the age of four years when she fell backward from a high chair and struck her head against the leg of the table. This injury was followed by "concussion of the brain" and on recovery she seemed all right except that about once a week she had a severe fit, which often lasted, according to her mother's account, for 12 hours, leaving her exhausted for a day or so afterwards. These fits were preceded by spasm of the right arm and leg. In time the mother noticed that the child's mental faculties were stationary and that she seemed to receive no new impressions of any kind. She called all strangers by names familiar to her before her accident and would, if asked where she lived, mutter something which her mother translated as being the address at which she had lived when she received the injury, although the family had removed several times since then. She could not be trusted away from her mother as she had a boundless genius for mischievous destruction.

On July 16th I operated. The nurse in attendance had had some very bad quarters of an hour preparing her for operation and was black and blue in her chest and arms from blows and pinches I trephined over the seat of the depression and found the meninges enormously thickened and adherent I opened the dura mater by a crucial incision and passed a trocar and cannula into the brain substance in several directions, but no fluid of any kind was obtained. I then cut away the exposed dura mater and separated the adhesions round the hole made by the trephine as well as I could with my finger. The disc of bone was not replaced and the scalp wound was completely closed by sutures.

Recovery from the operation was uninterrupted and from that time until the time of writing (Sept. 2nd) there has been steady improvement in every way. The fits have never returned nor has there been any spasm of the arm or the leg. Her mental condition has so improved that she can be trusted to go shopping for trifles for her mother. She has been left in the house for hours at a time with only her younger brother—which, in my opinion, is a risky proceeding—and has been "as good as gold." She calls me "the doctor" and addresses other people by their right names. Her gait is no longer shambling. She amuses herself for a long time together by looking at pictures and she is learning the names of animals, &c., with the facility of an average child of four or five years of age.

Bitterne, Hants.

NATURE'S ALKALINE TREATMENT OF GOUT AND RHEUMATISM BY THE USE OF NATURAL ALKALINE THERMAL WATERS.[1]

By CARL N. BRANDT, M.D.,
RESIDENT PHYSICIAN, HOT SPRINGS, VIRGINIA, U.S.A.

MY only excuse for attempting any addition to the already overdone subject of rheumatism and gout is that in an experience of a number of years in the treatment of these conditions solely certain clinical facts have been impressed upon me to so great an extent that I feel that the lessons learned by clinical work may be of some value to those of the profession who are called upon to deal with the subacute and chronic forms of so-called gout and rheumatism. To go into the theories that have been advanced in the past is not my purpose, but merely to try to show why and how results are obtained by the use of natural alkaline thermal waters, internally and externally, in a large number of cases where all other means had failed. That such is the case can, I am sure, be testified to by almost all the leading medical men of the day, and my only surprise is that they fail to understand how such results are obtained. No treatment gives rise to so much disbelief as the use of water as a therapeutic agent, and the idea that after the use of all the drugs, the so-called specifics, the alkalies, and the salines, relief should be given by the use of water is by many considered absurd, and the man who advocates such treatment is dubbed a fanatic. The profession, as a rule, may be said to be satisfied that the most approved treatment for these conditions is the so called alkali treatment, and yet they express surprise that good results should be obtained by the use of alkaline waters. Have they ever stopped to consider that, after all, the so-called water cures or treatment for gout or rheumatism are nothing more or less than the alkaline treatment, differing only in the fact that the alkali is, on the one hand, supplied by the druggist, and on the other by nature? Such is the case. All the water cures for these conditions consist in the use of alkaline waters, not only internally, but also in the form of baths. The use of the alkaline waters is but one factor in the proposition. Another is that when properly used we have the application of the alkaline treatment under the best circumstances and with the best possible surroundings. Quite possibly the patient's physician at home will have laid the fullest stress upon the proper diet, exercise, mental rest, &c., that the patient is to have, in addition to the medication advised, but (and herein lies the kernel of the nut) the patient does not follow these instructions. He will take his pill or teaspoonful of medicine with absolute precision and regularity, but he has no time for exercise and dieting. After finishing his business and following his pleasure he may give these a half-hearted attention for a day or two, but there it, as a rule, ends. These are not conditions to be helped solely by medication. On the other hand, when taking a so-called cure he not only has his medicine—i.e., alkaline water internally and externally—but having no business to attend to, no pleasures to follow, his one occupation is to conscientiously carry out in every detail his *régime* as laid down for him by his adviser, who has him constantly under observation. Given, then, the alkaline treatment—i.e., in this case supplied by use of alkaline waters, good air, a carefully regulated diet, proper exercise, absolute cleanliness, free action of the skin brought about by the use of the alkaline baths, and free action of the kidneys and bowels due to the internal administration of the alkaline water—added to the knowledge which the patient has that he is doing that for his condition which is best, can any patient fail to improve?

The first clinical fact which has been impressed upon me is the absence of any clearly defined line of demarkation between the symptoms of cases which have presented themselves in which a diagnosis of either rheumatism or gout has been made. I have been unable to demonstrate to my own satisfaction any different pathological condition in these so-called diseases, the clinical picture in either case being practically the same. The diagnosis, it would seem, is most often settled by the exciting cause. On the one hand, if the initial attack followed exposure to cold, dampness, &c., we are most frequently told that it is a case of rheumatism. If, on the other hand, the primary attack was apparently induced by excesses at the table or by indigestion we are said to have a case of gout. The absence of difference in the symptomatology and pathology of the many cases which have come under my observation of so-called rheumatism and gout has led me to discard the terms "rheumatism" and "gout" and bring these conditions under the one general head of "uric acid toxæmia." My own belief being that in the absence of any clearly defined pathological condition neither rheumatism nor gout are true diseases, but are groups of symptoms arising from improper metabolism, or in other words, the effects produced by the retention in the system of the products of metabolism, or waste, I am strengthened in this belief by the observance of two clinical facts. First, that in all the cases which have come under my personal observation in which either a diagnosis of gout or rheumatism has been made, the retention of uric acid has always been readily demonstrated. Secondly, that immediately the free excretion of uric acid was brought about the symptoms have disappeared, irrespectively as to whether the diagnosis has been rheumatism or gout. My universal experience has been that on presentation the so-called case of rheumatism or gout is found to be excreting less than the normal amount of uric acid, and after being put under treatment this amount gradually increases, and with its increase a diminution of the symptoms. The amount of uric acid excreted under treatment is frequently found to be twice or three times greater than before treatment was begun, and then gradually diminishes until the normal mark is reached, at which it remains so long as the patient continues so to conduct his life and habits as will insure his maintaining a proper relation between waste and repair. The ground being taken that uric acid retention is the indication at least, if not the prime factor in the causation, of such a condition or conditions, which I name "uric acid toxæmia," it follows that the knowledge of the exact amount of uric acid daily excreted is most essential. The ordinary routine of instructing a patient to bring to his medical man "a bottle of urine," with no instruction as to amount or how and when the same is to be collected being given, is useless.

Neither a qualitative analysis nor a microscopic determination will suffice—the first owing to the fact that that particular portion of the daily amount of urine may contain a greater or lesser percentage or the entire output of uric acid; the second owing to the fact that the drop or drops examined may contain all or none of the crystallised uric acid present, and thus lead to error in judging the amount excreted. Obviously a quantitative analysis is necessary. My procedure is as follows. A thoroughly clean glass vessel large enough to contain the output of urine for 24 hours is given the patient, with instructions to collect all urine passed for the following 24 hours; he is also instructed to first empty the bladder whenever having a bowel movement, so that no urine may be lost. From this a quantitative analysis is made, no change of diet having been ordered up to this time. From the evidence gathered from this first analysis treatment is the following day begun, and the patient is instructed as regards diet, exercise, and the use of the waters. On the day following a second analysis is made, the treatment as regards diet, baths, &c., being changed in accordance with the results of uric acid excretion as shown by said analysis. Analyses are continued every two or three days throughout the treatment which is ended when the excretion of uric acid has reached the normal, the patient then being allowed to return to his home after having been instructed as to his manner of living so as to maintain a proper excretion of uric acid. A record of the amount of uric acid excreted is kept in each case from day to day, and on this record, as I have said, is based any change in diet, baths, &c. It is not claimed that the use *of the alkaline treatment as supplied by nature is a specific*, but that its employment, owing to the conditions by which it is surrounded, gives a larger percentage of good results. In my experience I may say that next to the internal administration of the alkalies and their external application in the form of baths diet plays the most important part, and by which Haig has shown and my own experience has

---

e controlled. A dietary is to

y set rule to be applied to all

new diet to each patient in

as shown by the urinary analysis, remembering the importance of personal individuality.

The utility of the alkaline bath has been a vexed question, many practical men holding that there is no absorption of the mineral contents of the water, and many experiments have been made to prove this. My own experience leads me to believe that the taking of the alkaline baths alone will induce an increased uric acid excretion, my theory being that we here again have applied that old physical law of exosmosis and endosmosis, an acid condition of all the tissues, an alkaline medium—i.e., the bath—and an animal membrane—i e , the skin—intervening. The alkaline treatment, as supplied by alkaline thermal waters, I use in the following manner. A patient is given a daily alkaline bath, varying in temperature from 90° to 105° F., for a period of from 5 to 25 minutes. He is given none but alkaline water to drink, a portion being taken on an empty stomach. He takes from two to four hours' acti

ordered him. No f

factors of the tre

of uric acid as shown by the analyses. The results in an *experience of a number of years*

I would call attention to the

the use of alkaline water for t

toxæmia: (1) frequent quantitative urinary analyses; (2) changing the diet, the amount of exercise, and the amount of water taken until there is a free excretion of uric acid; (3) the taking of sufficient exercise for the thorough oxidation of the foods taken; (4) the putting aside of all mental work; (5) a specific diet ordered, not depending upon the patient's knowledge as to what contains or does not contain the proximate principles which are to be avoided; and (6) to teach the patient what nature's laws are as pertaining to his health and well being and how to follow them.

In conclusion, let me deny the statement that has so often been made that there is a great difficulty in making patients follow stringent rules. Such has not been my experience when I have had ability sufficient to impress them with the importance of these restrictions This treatment, as I have tried to show, is in no way specific It is not claimed that there is any magic in the waters used, but that it is merely an application and use of the recognised utility of the alkalies, augmented by the surroundings and conditions possible when the patient is so placed as to be constantly under the observation of his physician. The treatment is a rational one and a true exponent of the practice of physiology—a step I trust towards brushing away some of the *mysteries* which, unfortunately, have surrounded many medical measures I hope in the near future that it may be said of our profession, "*They practise physiology* and not medicine"

Virginia, U.S.A.

THE WEDGE OPERATION FOR ENTROPION AND TRICHIASIS.

By H. HERBERT, F R C S. Eng ,

MAJOR, I M S.; ACTING OPHTHALMIC SURGEON AND PROFESSOR OF OPHTHALMOLOGY, GRANT MEDICAL COLLEGE, BOMBAY.

WITHIN the space of one and a half years, some years ago, I operated on 130 upper lids for entropion and trichiasis by Snellen's method, slightly modified, with excellent results A large majority of the cases requiring it were those of combined entropion and trichiasis, some of them being very bad cases indeed The ordinary Snellen's operation is insufficient for many of our old neglected cases, and success in these depends entirely on the observance of the details pointed out below. If the necessary rules are followed the operation is equally suited to the mildest and to the most severe cases, to trichiasis as well as to entropion. The ordinary operation consists simply in the removal of a wedge of tarsus with its overlying muscle, the necessary incision having been made through the skin, and the parts are adjusted by Snellen's suturing. The points on which I wish to insist are as follows:—

1. A strip of skin two millimetres or more broad should be cut away, at least in all bad cases, unless the skin be contracted and scanty Otherwise it is redundant afterwards and the upper lip of the wound tends to overhang the lower. It leads to no shortening of the lid beyond that produced by the excision of tarsus.

2. (*a*) The depth of the tarsal wedge removed should in all cases be sufficient to divide completely the tarsus. If the conjunctiva be penetrated in places no harm results. The whole thickness of the tissue being divided it is found that the conjunctiva and subconjunctival tissue are sufficiently loose or extensile to permit of very considerable displacement as well as rotation of the lower segment of tarsus, which carries with it, of course, the border of the lid. (*b*) The breadth of the wedge at its base depends largely on the degree of entropion existing. When the lower portion of the tarsus is *much thickened and bent the rounded* swelling of its anterior surface renders it an easy matter, and indeed almost imperative, to remove a broader wedge than usual. But in some of the older cases of entropion the tarsus is much contracted vertically and the thickening involves the whole or greater part of it. Care has to be taken in these cases not to remove too much or the wedge may easily be made to include the greater portion of the tarsus. (*c*) The position of the wedge is important. The strip taken should be as near the free margin of the lid as possible—i e., immediately above the roots of the eyelashes Thus we have *uite a narrow strip of* tarsus left below and a comaratively broad plate above, so that when the anterior urfaces of the two are drawn together any displacement which may occur will be in the lower and not in the upper piece. The broad plate above affords a fixed basis from which one can work on the more readily moved and more readily moulded narrow marginal strip, with sutures.

3 It is in the suturing that Snellen's operation most distinctly fails to make the most of its opportunities (Fig. A.) The sutures should be entered as in Green's operation. The curved needle is to be introduced a little behind the most posterior lashes, wherever they may be situated, and passed obliquely forwards and upwards, to be brought out immediately above the lower margin of the skin wound Thus the more the trichiasis or districhiasis the further back will the point of entry be, and when the sutures are pulled upon the more will the border of the lid be *brought forward*. (Fig B) The needle should then be passed into the anterior surface of the upper piece of tarsus distinctly above the cut surface, and brought out again after taking a firm hold; neither skin nor muscle is taken up Introduced into the tarsus thus the sutures when tightened have distinctly more effect in bringing the eyelashes forward than when introduced "through the upper lip of the tarsal less of

Pepper to see her with the view of advising an interscapulo-thoracic amputation. This being agreed upon, and the aspect of affairs being fully explained to the woman and her husband, the operation was performed on Feb. 15th. A stimulating enema having been given and ether having been administered the clavicle was sawn across in its inner half and the vessels were tied with silk. In the shaping out of the flaps all the skin of the acromial and pectoral regions that was unimplicated in the ulceration was saved, and when it had been raised the pectoral muscles, the serratus magnus and latissimus dorsi, the levator anguli scapulæ, rhomboids and trapezius, and the cords of the brachial plexus were divided, and the "part" was taken away. Bleeding vessels were secured as they showed themselves, and without any waste of time the flap was adjusted and sutured, bulky dressings were applied with compression, and the patient was taken back to her warmed bed. She was much collapsed in the evening, but at once answered to the injection into the veins of a quart of hot saline solution which was promptly given by Mr. G. D. Maynard, the house surgeon. She made a rapid recovery and when she visited the hospital a month or two later she looked extremely strong and healthy; moreover, she expressed herself as being well satisfied with the result of the treatment which she had undergone.

Remarks by Mr. OWEN.—As a rule the interscapulo-thoracic amputation is performed for malignant disease, and especially in cases of recurrent mammary scirrhus where any less extensive operation cannot be resorted to. Mr. F. Treves has also done it for gunshot wounds in South Africa. I am not sure but that this is the first report of the operation being resorted to for the cure of a patient with intractable ulceration after a burn.

The woman had a narrow chest of what Sibson called the "expiratory type," and the experience which I met with during the operation suggested that if I were describing the steps of the operation in a work on operative surgery I should insert a few lines to this effect, that in a thin, narrow-chested subject—and especially when the arm has been long hanging by the side—the subclavian vessels as they rest upon the first rib must be sought for at a very considerable distance above the level of the clavicular incision. Indeed, in my case I found that I could best reach them by making a vertical incision up into the root of the neck.

MONSALL FEVER HOSPITAL.

A CASE OF PNEUMONIA (DOUBLE); EMPYEMA; ABSCESS IN THE ABDOMINAL WALL.

(Under the care of Dr. R. W. MARSDEN.)

AT the Carlisle meeting of the British Medical Association the late Mr. William Anderson drew attention to the surgical importance of the sub-peritoneal space. He showed that it was a frequent site for new growths, and that in it formed many abscesses, such as the remarkably extensive one which is described below. In that case the septic infection probably came primarily from the empyema or the pneumonia, and made its way through the diaphragm, perhaps by one of the normal openings in that muscle; it then found itself in the sub-peritoneal space, where it spread easily amongst the soft areolar tissue.

A girl, aged 11 years, was admitted into the Monsall Fever Hospital on June 13th, 1900, with signs of pneumonia at both bases. The history stated that she had been ill for three weeks commencing with headache, and that she had subsequently frequent vomiting and diarrhœa. The temperature was 104·4° F. on admission and during the next three days it fell by lysis to 100°. As the spleen was enlarged to percussion and palpable a diagnosis of enteric fever complicated by double pneumonia was made, but an examination of the blood serum for Widal's reaction gave a negative result. In the meantime the pneumonic signs at both bases had spread over a larger area, and by June 20th, as a marked remission in the temperature had occurred on three consecutive mornings and as the percussion note at the bases gave the impression of increased solidity, a diagnosis of early empyema was made, but since the bronchial breathing at each base was loud and clear, an exploratory puncture was deferred. Between June 20th and 29th the morning temperature averaged 99° and the evening temperature 103°, and the physical signs at the bases seemed to be quite at a standstill. The patient complained, however, of abdominal pain, which was thought to be of pleuritic origin, since though the abdomen was full and somewhat tense, with a girth at the umbilicus of 20⅞ inches, there was no tenderness or hardness and percussion revealed no unusual want of resonance. It was, however, noted that respiration was of the costal type.

As the patient seemed to be rather worse an exploratory puncture was now made into the right pleural cavity posteriorly, and a syringeful of yellow, creamy, non-odorous, thick pus, of uniform consistence and free from lymph particles, was withdrawn. From the left base also a few drops of purulent material were obtained. Accordingly a piece of rib was removed from the right side, but only two ounces of pus with the characters above mentioned were evacuated. Up to July 3rd the remissions were daily becoming less, and their continued presence was attributed to a small quantity of pus in the left pleura. On the evenings of July 3rd and 4th the temperature was 102·4° and 103° respectively, and on the morning of the 5th the patient was very decidedly worse. During the preceding night she had passed six watery brown stools and had vomited frequently. (It should be mentioned that on two previous occasions—viz., June 20th and 27th—she had vomited, and that throughout the period of observation in the hospital, though the bowels had acted on an average once daily, yet the stools had been very variable in consistence.) She was now lying with her legs flexed upon the abdomen; there was, however, no pain on palpation and no sign of hardness or localised fulness, but a general feeling of tenseness and elasticity. The dulness of the liver and spleen was quite distinct, and percussion of the rest of the abdomen gave a perfectly resonant note. Measurement of the abdomen at the umbilicus showed an increase to 22¼ inches, and fluctuation could be obtained from one side of the hypogastrium to the other, but not when pressure was made in the middle line.

Though unable to diagnose the condition of the abdomen, as the patient was so much worse it was decided that exploration was indicated. Accordingly an incision was made in the middle line below the umbilicus. Immediately the sheath at the posterior surface of the rectus abdominis was divided thick yellow pus with the characters already described began to well up into the wound. On inserting the finger it was evident that the pus proceeded from a shallow space between the peritoneum and the transversalis fascia. The outlines of this space could not be determined though a probe was passed almost to the costal margins above and to the extreme flank on each side. No less than 35 ounces of pus were measured, and by inserting a large drainage-tube from the central incision to a counter-opening in each flank, a free exit for the remainder was provided. The patient immediately began to improve and ultimately left the hospital on Sept. 11th, 1900.

Remarks by Dr. MARSDEN.—The uniform distribution of such a large quantity of pus over the front of the abdomen gave so little alteration in the usual physical signs that I have to confess that I did not suspect its presence in that situation, and it is especially on account of the consequent possible difficulty in diagnosis that I have thought the case worthy of record. As regards its origin I am of opinion that it was subsequent to the double pneumonia, both from the course of the disease and the character of the pus, but as I have not previously seen or heard of such a condition, I should be pleased to have information from any readers of THE LANCET who have had a similar case.

BIRMINGHAM GENERAL HOSPITAL.

TWO CASES OF "TRAVELLING" FOREIGN BODY.

(Under the care of Mr. T. F. CHAVASSE.)

IN the Mirror of Hospital Practice in 1898[1] we published an account of a case in some respects resembling the first of the two cases described below; a piece of steel passed from the stomach into the subcutaneous tissue of the abdomen whence it was removed by Mr. John H. Morgan. In Mr. Chavasse's case the shawl-pin probably perforated the wall of some part of the small intestine. For the notes of the cases we are indebted to Mr. R. E. Sedgwick.

CASE 1.—A girl, aged three years, was admitted to the

---

[1] THE LANCET, Feb. 5th, 1898, p. 365.

Birmingham General Hospital on May 28th, 1900, with a history of having two months previously swallowed a brass shawl-pin. She complained of abdominal pain on movement, and on examining the abdomen a definite tumour of about the size of a hazel-nut could be felt, half an inch outwards and downwards from the umbilicus on the left side. This was painful on pressure and on deep expiration. A long pin, with its head pointing upwards, was seen when the child's abdomen was examined with the fluorescent screen. On June 1st Mr. Chavasse made a small incision over the tumour and at half an inch from the surface came upon dense fibrous tissue surrounding a small collection of pus, in which the pin was lying. The pin on extraction was a large brass shawl-pin two and a half inches in length. The child made an excellent recovery and was discharged from the hospital ten days later. At no time was there any trace of fæcal matter, although the pin had apparently ulcerated through the intestine into the abdominal wall.

CASE 2.—A man, aged 23 years, was admitted into the Birmingham General Hospital on August 7th, 1900, with a red œdematous swelling over the front of his neck in the middle [illegible] for two inches He had some [illegible] His history was [illegible] while going fishing, he [illegible] something in his throat which almost choked him, but which passed away after five or six minutes." Three days later his throat became sore and he attended the hospital and was given medicine and gargle which relieved him. Five days previous to admission his throat began to swell and had gradually increased. An incision one and a half inches long was made in the middle line below the level of the cricoid cartilage. No pus was found although Hilton's method was extensively used Hot boric fomentations were applied and two days later a fair amount of thin pus was discharged and his temperature fell to normal. The swelling went down and the incision healed, except a small sinus, which continued to discharge from 15 to 20 minims of pus a day. He went out, the sinus continuing in the same condition till Sept. 22nd, when on squeezing it the husk of an oat was discharged. The sinus closed three days later. This husk had apparently got caught in the larynx, possibly in the ventricle, and had ulcerated through into the tissues of the neck, to be finally discharged through the skin.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Oct 26th, Sir R. DOUGLAS POWELL, the President, being in the chair.

The new arrangements for the exhibition of cases, referred to in a previous number of THE LANCET, were adopted for the first time on this occasion

Mr. J. JACKSON CLARKE showed a male patient, aged 56 years, from whom one and a half years ago he had removed the greater part of the [illegible] with by a modified Kraske's op[illegible] of the operation necessitated le[illegible] bowel open in the mid-posterior line To remedy the incontinence thus caused Mr. Clarke, four months ago, closed the gap by a plastic operation, the chief features of which were: (1) freshening and completely freeing the bowel; (2) denuding the surface to the left of the gap by dissecting off a strip of skin and fat; and (3) mal[illegible] side of the gap and fixi[illegible] mattress sutures to the [illegible] side and its edge to the [illegible] The operation had answered its purpose perfectly The patient was now in good health and free from any sign of local or metastatic recurrence of the original growth —Mr. CHARTERS J SYMONDS congratulated Mr Clarke on the admirable results achieved and suggested that an illustration and diagram of the case should be added to the description of the operation for the Transactions of the Clinical Society.

Dr J WALTER CARR exhibited a case of Myositis Ossificans Progressiva. The patient was a boy, aged seven years The symptoms were said to have been noticed only eight months and the patient had been under observation for five months, during which time the disease had made very little progress There was extensive ossification of the dorsal muscles, of the pectorals, the latissimus dorsi, the biceps, and the left rectus abdominis. The back was almost rigid, the movements of the shoulder and elbow-joints were greatly restricted, and respiration was mainly diaphragmatic. There [illegible] e of the forehead (following upon [illegible] of the right hand, just below the [illegible] each tibia, on the left internal malleolus, and on the proximal phalanx of each great toe Beneath the skin below the spine of the left scapula was a flat piece of bone over two inches long. The great toes were, as usual in these cases, shortened and turned outwards, and only one phalanx could be felt in each. The thumbs were normal

Mr. HERBERT TILLEY exhibited a case illustrating the Radical Cure of Chronic Frontal Sinus Empyema. The patient was a female, aged 50 years, who had complained of purulent discharge from the left nostril of five years' duration, with occasional attacks of severe frontal headache, "dryness of throat," and unpleasant taste and smell. When she came under the care of Mr. Tilley in April, 1900, the left nasal cavity was full of polypi bathed in pus. These were removed. Exploration of the maxillary antrum showed a small quantity of pus present and this was drained by the alveolar method. The anterior half of the middle turbinal was next removed, followed in the course of 10 days by external radical operation upon the frontal sinus. The patient left the hospital quite cured 21 days after the operation There was no discharge from the sinus at present and the case showed how very unnoticeable was the external scar, although practically all the anterior wall of the sinus had been removed.

Dr. STCLAIR THOMSON exhibited a man, aged 40 years, with Growth of the Left Tonsillar Region It was first noticed in June last The anterior pillar of the fauces on the left side was occupied by a new growth which spread in various directions The margin was well defined. The surface was flat and irregular and did not feel hard to the finger. There were no enlarged glands and no pain; the tongue was protruded easily, although the growth had affected its base. There was no history of specific infection and the condition had been unaltered by the administration of mercury and iodide. (A section was exhibited under the microscope)—Mr. TILLEY suggested applying salicylic acid to the papillæ (which were the seat of a curious horny change) in the same way as to a corn. It would probably be efficacious.—Mr. CHARTERS SYMONDS expressed the view that the growth beside the tonsil was an epithelioma in spite of the small amount of infiltration. He had seen similar cases where the growth appeared like a plaque and was only just visible to the laryngoscope. He did not think it would be possible to completely eradicate the growth without removal of the upper jaw. Caustics would not be of any use.—Mr. JACKSON CLARKE was decidedly of opinion that it was epitheliomatous and should be removed at once —Dr. STCLAIR THOMSON, in reply, said that the case was somewhat atypical. Tuberculosis had been suggested as a diagnosis. He had watched the case for three months but had not come to any conclusion as yet.

Dr. PERCY KIDD exhibit[illegible] Disease of the Knee-joint ([illegible] inly due to enlargement of the articular ends [illegible] by the radiographs. [illegible] the joint was swollen [illegible] red and shiny. Ther[illegible] crepitus could be recognised on manipulation. Numerous bruises were seen on various parts of the body as the result of slight injuries During the first fortnight there was an irregular remittent pyrexia (from 103° to 99° F.), but since then the temperature had been normal With rest in bed and application of splints the pain and tenderness of the joint disappeared and the swelling diminished There was a history of injury to the joint five days before admission. Profuse bleeding from slight cuts and injuries had occurred repeatedly from an early age.—Dr. A E SANSOM remarked that it was not unusual to find joint affection with hæmophilia but its nature was obscure Sometimes it was thought to be rheumatic and sometimes tuberculous In this case there was at the present time no his address, which was seconded by Dr. **Macfie Campbell** and carried with acclamation.

Strangulated Femoral Hernia.—Trephining for Meningeal Hæmorrhage.—Pneumonic Consolidation.—Pulsus Paradoxus.—Myelopathic Albumosuria.

The second meeting of the session of this society was held on Oct. 25th, Mr. **Edgar Browne**, the President, being in the chair.

Mr. G. P. **Newbolt** read notes of two cases of Strangulated Femoral Hernia in which he had resected the bowel, using Murphy's button to approximate the ends. One occurred in a woman, aged 70 years, and the other in a man, aged 41 years. Both recovered, the button passing in the first case in 18 days and in the second case in 24 days.—Mr. F. T. **Paul** said, notwithstanding the success which had attended the use of Murphy's button in Mr. Newbolt's cases, that these sort of appliances were daily losing favour. They had served an excellent purpose in teaching surgeons the importance of accurate and water-tight approximations and they shortened the time occupied by the operation, but they managed to unite bowel and stomach wounds now both accurately and quickly with simple suture and by so doing avoided the risk of the presence of a foreign body lying in contact with the wound, a risk which had caused many fatalities. Recently he had only used the button when the difficulties attending sutures were unusually marked.—Mr. R. W. **Murray** remarked upon the difficulty there was in knowing how best to deal with the injured gut, whether to return it or to excise it, and suggested that in all cases of doubt it would be better to excise it. He related a case of strangulated hernia (inguinal) in which he had successfully removed a gangrenous portion of small intestine, uniting the cut edges by simple suture—a method he much preferred to the use of Murphy's button.

Mr. **George Hamilton** related a case of successful Trephining for Meningeal Hæmorrhage. A boy, aged eight years, while running along with his hoop fell on the pavement; though feeling a little sick and vomiting once he played about until bedtime. Next morning he appeared to be well, but became drowsy and unconscious the following day. The main features in the case were: (1) the considerable period elapsing between the accident and the symptoms; and (2) the marked dilatation and fixation of the left pupil. These led to the almost certain diagnosis of hæmorrhage. The boy made an excellent recovery and never had a rise of temperature.—Mr. W. **Thelwall Thomas** drew attention to the importance of dilatation of the pupil in extra-dural hæmorrhage as an indication of cerebral pressure in the middle fossa of the same side; if, on trephining and removal of the extra-dural clot, oozing of blood still proceeded from deeper down and light gauze packing failed to arrest it the external carotid artery should be tied.

Dr. C. J. **Macalister** directed attention to cases of Pneumonic Consolidation which, after running a very chronic course, resolved immediately, after exploratory puncture with an aspirator needle. This sequence of events had occurred so frequently in his experience that he had come to regard it as something more than coincidence. He related cases in which it had happened and in which recovery had quickly followed the puncture, and he also referred to a case of consolidated lung associated with fever of several weeks' duration in which improvement leading to hope of recovery ensued, but which afterwards proved to be the result of some malignant trouble connected with the liver from which the patient ultimately died.—Dr. W. **Blair Bell** said that he had a case recently where unresolved lung existed 14 days after croupous pneumonia. Puncture with a trocar brought about rapid resolution. He thought the reason for the cure was explicable if the comparison was made between lung in a state of inflammation and inflammation in any other part of the body where the knife or needle gave rapid relief, probably by causing a flow of blood from the inflamed part, thereby relieving the congestion and condition of stasis which occurred in the course of inflammation and so bringing about resolution. It was advisable to use a large puncturing instrument, such as a trocar, to insure bleeding, and to adopt this method of treatment as soon as ordinary natural resolution seemed improbable.—Dr. T. R. **Bradshaw** said that he wished to draw attention to the manner of operation. It was never desirable to use an exploring syringe with a small needle, because if fluid were found the aspirator would have to be employed and so the patient would be put to the pain of two punctures instead of one, or, on the other hand, the fluid might be too thick to run through the small needle, hence a fairly large needle connected with an aspirator should be used.

Dr. **James Barr** read a note on the so-called Pulsus Paradoxus and also on a case of Myelopathic Albumosuria.—Dr. **Bradshaw** said that Dr. Barr's was the twelfth undoubted case of myelopathic albumosuria which had been thoroughly investigated, and that now that the condition was more generally understood cases were becoming more frequent. The records showed that it was a disease of the second half of life and all but one of the recorded cases were in males. The first symptoms were generally associated with bone lesions, but there was reason to believe that the presence of albumose could be detected at an early period if it were sought for. It was highly important to distinguish this form of albumosuria from that which was often found in pneumonia and other inflammatory conditions and which the late Sir William Roberts called peptonuria. The form under consideration was always associated with a cellular infiltration of bone known as multiple myeloma, but the manner in which they were related was at present merely a matter of conjecture. The term "myelopathic albumosuria" was a convenient one to express the association.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Inaugural Address by the President.—Aneurysm of the Coronary Arteries of the Heart.—A Method of Intestinal Suture for Gastro-enterostomy and Enterectomy.—Exhibition of Cases and Specimens.

The opening meeting of the session of this society was held on Oct. 19th, Dr. **Gordon Black**, the President, being in the chair.

The **President** gave his inaugural address on Some of the Duties of Members of the Medical Profession to Each Other.

Dr. **Wardrop Griffith** read a paper on Aneurysm of the Coronary Arteries of the Heart and showed specimens illustrating it.

Mr. H. **Littlewood** advocated a method of Intestinal Suture for Gastro-enterostomy and Enterectomy by excising a portion of the mucous membrane and then uniting the cut edges of the stomach and the intestine by means of a continuous cat-gut suture, interrupting the suture by knotting it at two equi-distant points. The parts were clamped and held in apposition by Doyen's clamp forceps—these guarded by rubber tubing made admirable intestinal clamps—an incision was made down to the mucosa, an elliptical portion of the mucous membrane was excised, and the coats were separated for a short distance from the mucosa. This method prevented the troublesome closing sometimes occurring after gastro-enterostomy, and both in this operation and in that of enterectomy it allowed a broad surface consisting of all the other coats to be easily united by the continuous suture. It was not found necessary to bring the two serum surfaces in contact along the whole line of suture. Mr. Littlewood preferred a small curved Hagedorn's needle used on the flat to any special needle and chromic gut for suturing. (Mr. Littlewood showed a woman, aged 51 years, on whom he had operated three months ago, removing the cæcum for malignant disease and uniting the ileum to the ascending colon by the method described. He also referred to five cases of gastro-enterostomy successfully performed by this method.)

The following cases and specimens were exhibited:—

Dr. **Wardrop Griffith**: A man with great Œdema of the Eyelids together with some Œdema of the Forehead. There was no visceral disease and no history of erysipelas. The œdema was remarkably firm.

Mr. **Constable Hayes**: A case of Multiple Odontomata probably in connexion with the Bicuspids, which were all missing.

Dr. E. F. **Trevelyan**: A case of Functional Tremor simulating Paralysis Agitans in a man, aged 28 years. The tremor was of three years' standing. It sometimes ceased completely when the patient supposed that he was not being observed and there were no other symptoms of paralysis agitans.

Mr. **Mayo Robson**: (1) Cæcum removed for Tuberculous Disease producing Stricture at the Ileo-cæcal Valve; (2)

Cæcum removed for Cancer of the Ileo-cæcal Valve; (3) Extra-uterine Gestation Diagnosed and Removed at the Eighth Week, before Rupture; (4) Microscopical Section showing Interstitial Pancreatitis; and (5) a Specimen of a Recurrent Papilloma of the Bladder illustrating its Infectivity.

Mr. A. E. LITTLE: (1) A Slide showing the Plague Bacillus; and (2) Photographs of Plague Hospitals.

Dr. C. M. CHADWICK: (1) Splenic Leucocythæmia (specimen of blood shown); and (2) a Stomach, much Elongated, with Hour-glass Contraction (death from tetany).

Dr. ALLCOCK (Goole): Cystic Dilatation of a Corpus Luteum.

Mr. BASIL HALL (Bradford): A Perfect (?) Method of Sterilising Catgut.

Dr. A. L. WHITEHEAD: (1) Cavernous Angioma of the Orbit; (2) Epithelioma Auris; and (3) a Superior Cervical Ganglion of the Sym[illegible]

Mr. H. LITTLEWC[illegible] Disease, with End-[illegible] specimen); (2) A c[illegible] [illegible] years.

Dr. A. G. BARRS: (1) A case of Obstruction of the Superior Vena Cava; [illegible] tonitis with Secondary [illegible]

Mr. B. G. A. MOYNII[illegible] Uterus removed by Vaginal Hysterectomy; (2) Fibroid Uterus removed by Vaginal Hysterectomy; (3) Vulva and Portion of the Vagina removed for Carcinoma; and (4) Primary Carcinoma of the Vagina.

Mr. LAWFORD KNAGGS Epithelioma of the Bladder springing from the Vicinity of the Prostate.

CHELSEA CLINICAL SOCIETY.—The opening meeting of the session of this society was held on Oct. 16th, when Dr. William Ewart, the President, delivered an address on "A Clinical View of some of [illegible] and its Valves," of which t[illegible] He commenced by observing [illegible] congratulated upon the useful [illegible] large share of the success which had been achieved was to be ascribed to the energy of the retiring president, Mr. Foster Palmer, and to the exertions of the senior honorary secretary, Dr. Austin Cooper. The special purpose of the address was to illustrate the methods applicable to the problems of cardiac disease. For the elucidation of the intricate questions connected with valvular defects and with their physical signs that which was most needed was a [illegible]d physiology. Where phy-[illegible]ll the information required [illegible]ned to account for the study [illegible] in disease. In spite of its [illegible] dependence upon theory to bridge over the gaps between definitely proved facts, and of the provisional character of its conclusions, that method possessed a solid strength in the never-failing supply of the unerring experiments of disease. In the course of a brief anatomical introduction a description of the more rigid apparatus of the bullock's heart with its two bony plates helped to throw light upon the existence and the functions of the two fibrous roots or fibro-cartilages of the aorta in the human subject, of which specimens were exhibited. The larger root had been described by Sibson as the central fibro-cartilage; but they both fulfilled essential functions not only as forming part of that internal axis for the intrinsic movements of the heart which it was possible to identify with the ventricular septum and the foot of the aorta, and as affording attachment to the auriculo ventricular valves and to the so-called "fibrous ring," but also as the means of bringing about those slight changes in the position and in the direction of the aorta which on careful inspection could be recognised in the fully contracted heart In connexion with the ventricular systole, the mechanism of which was compared to the action of hand-bellows, stress was laid upon the changes occurring in the "supra-papillary space" and the "aortic channel," whilst the "infra aortic space" remained patent Attention was called to the contrast between the recent views of Potain and those of Chauveau as to the function of the auricle during the preliminary stage of ventricular systole, the so-called "pre-systole." As regards the mitral mechanism it was suggested that since all hearts differed in their individual structure, differences might exist in the mode of closure, ranging between the two extreme types described as the "high closure" and "low closure," the latter being the normal type. The varied functions of the papillary muscles and of the chordæ and the myotatic theory of auriculo-ventricular peristalsis were discussed, and the production of the first sound was referred largely to papillary agency. Clinical illustrations were drawn chiefly from the varieties of mitral disease which at an early stage present little differentiation as regards lesions. An explanation was offered for the evolution of apparently identical changes into pure valvular incompetence in one set of cases and into pure stenosis in the other. The development of stenosis was more likely in young and healthy hearts with a thoroughly normal low closure, whilst incompetence resulted from opposite conditions The late stages of mitral stenosis were distinct in every way from the earlier stages. The mechanisms and the physical signs were largely influenced by the protrusion of the auricle into the ventricle. It was suggested that this complication might be connected with the production of the murmurs of stenosis, with the suppression of some of them at a later stage, and with the disappearance of the aortic second sound at the apex. The peculiar character of the pulse of compensated mitral stenosis seemed also capable of explanation upon the same lines, Most of the points which were brought forward were illustrated by specimens and diagrams.—A vote of thanks to the President, proposed by Dr. J. B. Ball and seconded by Dr. C. J. Harrison, was carried. It was resolved that the address should be published at the expense of the society.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The first meeting of the session of this society was held on Oct. 24th, Mr. W. B Holderness, J.P., the President, being in the chair.—The President showed the following radiographs: [illegible] Months after the Reductio[illegible] humerus split and broken; [illegible] case of Achondroplasia.—Dr. E. B. Hulbert showed (1) several drawings and photographs of Epidemic Eczema, one or two of which exhibited the dusky pigmentation of the skin following an attack; and (2) (by kind permission of Mr. J. R Lunn, of St [illegible] and photographs of [illegible] Melanotic Sarcoma, [illegible] Rodent Ulcer, and a Rare Eruption in a Case of Renal Disease —Mr. Clinton T. Dent (surgeon to St. George's Hospital) delivered an address entitled "Surgical Lessons of the War" After pointing out that the great interest evinced some months back in the surgical results of the war was already waning and that there was a risk of much of the valuable experience which had been gained being lost to posterity he said that experiments with small-bore bullets which had been carried out before the war did not conform closely with the results arrived at by practical experience. He considered that, well as the members of the Royal Army Medical Corps had worked, the system was capable of improvement, more particularly in the direction of the formation of an army medical reserve composed of men of active [illegible] standing. He suggested [illegible] to encourage a general [illegible] The mild character of the wounds had been greatly exaggerated in the press, but [illegible] provement upon the results o[illegible] favouring these satisfactory r[illegible] bullet, (2) the use of anti[illegible] condition of the men and [illegible] ing the Lee-Metford bull[illegible] velocities Mr Dent described the eccentric rotation of bullets which led to their retention in soft tissues even when no bone had been struck. Clean perforations of bones which abounded in cancellous tissue were common, but when the shaft of a long bone was struck the bone was broken up and expanded as well as fissured. Union usually took place in consequence with much callus Mr. Dent pointed out that wounds of great joints (the ankle excepted) did well, as also did head injuries in which trephining was frequently practised, and in every case it demonstrated the necessity of relieving the pressure on the brain from the splintered inner table, thus embodying the teaching of Ambroise Paré 350 years ago. He concluded a lucid and suggestive paper by insisting on the great difficulty of the surgical problems and on the need for long and minute study of them in order that a class of specialists in military surgery could be created.—Mr. S. Osborn (of the St. John Ambulance Brigade), who had been serving with the Van Alen Field Hospital attached to Lord Methuen's column, spoke in corroboration of the remark made by Mr. Dent that the surgical lessons of the war were of the greatest value as showing how much less serious were the injuries in the South African war than were those sustained in previous wars. This satisfactory condition he attributed largely to the pointed character of the Mauser bullet taken in connexion with the excellent antiseptic precautions adopted almost immediately on receipt of the injury. Having been present in the Turco-Greek war he was able to compare the injuries with those in the Boer war and he showed by comparing the Martini bullets with their blunt extremities which he had removed in the former war with the conical ends of the Mauser bullets of the present war what a much more formidable projectile the Martini bullet was as compared with the Mauser bullet. In conclusion Mr. Osborn hoped that someone would read a paper on the medical lessons of the war, as that was the side which demanded more special attention. It was also a question whether by the attachment of a skilled sanitarian to every army corps and the formation of a sanitary corps similar to those which were employed in continental armies the sanitary condition of the army in the field might not be improved and the terrible mortality on the medical side in future wars be considerably lessened.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in the Medical Institution, Liverpool, on Oct. 19th, Dr. J. B. Hellier (Leeds), the President, being in the chair.—Dr. H. Briggs (Liverpool) related a case of Tubal Pregnancy with formation of a tubal mole which had been retained in the unruptured Fallopian tube for four months, no hæmatocele being present. A tubal swelling was detected lying in the floor of the pelvis; this was removed by posterior vaginal section. The distended Fallopian tube was unruptured. The absence of hæmatocele was a feature of interest and Dr. Briggs believed that the tension in the tube had been limited by leakage of blood from the uterine end of the tube into the cavity of the uterus. On section the tube contained a mole with some fluid blood.—Dr. A. Donald (Manchester) related a case of Tubal Pregnancy in which a five months fœtus with placenta was removed by abdominal section. The patient, a woman, aged 40 years, had one child 16 years before. She complained of recurrent attacks of abdominal pain with amenorrhœa for nine months. The pain was only of six weeks' duration. The abdomen presented a diffuse fluctuating swelling, reaching from the pelvis to the level of the umbilicus. The uterus was considerably enlarged and could be felt lying in front and to the right of the swelling. Abdominal section was performed. A sac containing a living fœtus at five months' development was discovered; the fœtus was removed, amniotic fluid escaping. The placenta occupied the floor of the pelvis and was removed without difficulty from the broad ligament. Hæmorrhage was readily controlled by silk ligatures at the uterine and pelvic borders of the broad ligament. Dr. Donald considered that the placenta probably occupied the Fallopian tube, inasmuch as there had been no history of rupture. A few hours after the operation a very large decidual cast was expelled from the uterus. The patient made a rapid recovery.—Dr. Arnold Lea (Manchester) showed a Fallopian tube from a case of Extra-uterine Gestation with Hæmatocele. The ruptured tube was removed per vaginam after evacuation of a quart of clotted blood from the peritoneal cavity.—Remarks were made by Dr. Lloyd Roberts (Manchester), Dr. E. Stanmore Bishop (Manchester), Mr. R Favell (Sheffield), and others.—Dr. J. E. Gemmell (Liverpool) showed a Fibro-cystic Pedunculated Tumour of the Uterus removed by abdominal section from a patient, aged 32 years. The tumour had grown outwards between the layers of the broad ligament, but was removed without difficulty, the uterus remaining intact. The patient made an uninterrupted recovery.—The President showed:—1. A Uterus, Pregnant five and a half months, with Multiple Myomata. The patient, a woman, 33 years of age, had a tumour which filled up Douglas's pouch and which would have obstructed labour. Abdominal section was performed and the uterus with the tumours were removed by supra-vaginal abdominal hysterectomy. The patient rapidly recovered. 2. Bilateral Suppurating Ovarian Cysts removed by abdominal section from a patient who had suffered from septic puerperal infection after delivery 14 months previously.—Dr. E. T. Davies (Liverpool) read notes of three cases of complicated Ovarian Tumours. Case 1. The patient was a women, aged 58 years, with a history of recurring attacks of pelvic pain for several months. At the operation the pedicle had undergone torsion and numerous adhesions to the bowel and omentum were present. Case 2. The patient, a woman, aged 43 years, on whom ovariotomy had been performed 13 years previously, was suddenly seized with acute abdominal pain and peritonitic symptoms. A cystic tumour was felt in the pelvis. Abdominal section revealed an ovarian cyst with acute torsion of the pedicle and hæmorrhage. Both patients made good recoveries. Case 3. The patient, a woman, aged 53 years, had a solid tumour of the ovary, accompanied by ascites and the symptoms of acute peritonitis. At the operation no twisting of the pedicle had occurred, but the peritoneum showed evidence of acute inflammation. This patient, though extremely ill, with a temperature of 104° F. and a pulse of 140 at the time of operation, made a good recovery.

BEDFORD MEDICAL SOCIETY.—A meeting of this society was held on Oct. 25th, Mr. Jabez Carter being in the chair.—Dr. Henry Skelding showed a boy with Webbed Fingers, on one of which he had operated by Morton's method, and a boy with Keloid Scars which had followed an operation for lop ears performed in South Africa.—Dr. G. P. Goldsmith showed a skiagram of a case of Transverse Fracture of the Patella in which bony union appeared to have been obtained by fixation on a back splint for three months.—Dr. R. H. Coombs showed the Kidneys from a case of Anuria of 10 days' duration. The right kidney was hydronephrotic and useless, the left was hypertrophied and hydronephrotic, its upper third consisting of a bilocular sac which had no communication with the pelvis of the kidney. The left ureter was blocked by a calculus near its upper end. Both ureters were dilated and the bladder was hypertrophied. The symptoms were anuria and vomiting. An hour before death Mr. W. G. Nash cut down on the left kidney and evacuated four or five ounces of purulent urine from the cyst in the upper third of the kidney which presented in the loin.—Dr. Coombs also showed a woman with Molluscum Fibrosum and a man with Progressive Muscular Atrophy.—Dr. F. B. Willmer Phillips read notes of a child who had repeated attacks of Fever, which he attributed to gnat-bites.—Dr. H. Savory showed the Kidneys from a child, aged 10 weeks. They were the seat of congenital cystic disease. A previous child in the same family had died from this disease in 1898 and the kidneys were shown.—Dr. A. O. Hartley showed a Hairball from a Cow's Stomach.—Mr. W. G. Nash showed:—1. A Uterine Mole passed at six months. Growth had ceased at 10 weeks when a slight hæmorrhage occurred. The symptoms were amenorrhœa and pelvic discomfort. There was retroflexion of the uterus. 2. A Suppurating Dermoid Cyst removed from a woman, aged 41 years, who had borne six children without any difficulty in delivery. The pedicle had become twisted two turns and was nearly obliterated. This had caused hæmorrhage, suppuration in the cyst, and peritonitis around it. The patient made a good recovery. 3. A Papillomatous Cyst of the Ovary and an Annular Carcinoma of the Small Intestine which had been removed from the same patient. The symptoms were those of intestinal obstruction. A large, rapidly growing ovarian tumour was removed and at the operation the growth in the bowel was discovered. The growth with four inches of the small intestine and several glands in the mesentery were removed a fortnight later. Allingham's bobbin was used to connect the divided ends of bowel. The patient made an excellent recovery.—Mr. Nash also read notes of a Gastrojejunostomy performed for cancer of the pylorus. Murphy's button was used. The patient had been much benefited by the operation and had increased 20 lb. in weight in three months.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—The opening meeting of the session was held on Oct. 11th, when the President, Dr. E. Wearne Clarke, delivered his introductory address on Medicine in Fiction. Commencing by a brief reference to medicine as seen in pictorial art, [illegible] medicine and [illegible] particularly in the [illegible] as represented in [illegible]. Turning to the novelists the address next dealt with some of the medical men and medical incidents portrayed by Balzac, by Tolstoii in "Anna Karénina," and by Conan Doyle in "The Curse of Eve" and other works. The Doctor Lydgate of George Eliot's "Middlemarch" was next noticed at some length, and the address closed with reference to "The Diary of a Late Physician," by Samuel Warren; to "The Ralstons," by Marion Crawford (as an example of Transatlantic medicine); and finally, to "Ian Maclaren's" well-known Doctor Maclure in his book "Beside the Bonnie Briar Bush."

Reviews and Notices of Books.

Diseases of the Throat, Nose, and Ear; A Clinical Manual for Students and Practitioners. By P. McBRIDE, M.D., F.R.C.P. Edin., Fellow of the Royal Society of Edinburgh; Surgeon to the Ear and Throat Department of the Royal Infirmary; Lecturer on the Diseases of the Throat and Ear in the University and in the School of Medicine of the Royal Colleges, Edinburgh. Third Edition, revised and partly re-written. With Coloured Illustrations from Original Drawings. Edinburgh and London: Young J. Pentland. 1900.

THIS is a well-printed and handy manual of some 700 pages, furnished with a copious index. The first section dealing with affections of the larynx and pharynx occupies nine chapters. Eleven chapters are devoted to nasal affections and an equal number to diseases of the organ of hearing. The author wisely omits anatomical and physiological details, which can be studied in appropriate treatises, so that the bulk of the work is devoted to clinical material and details. The whole of the former work has been revised and in part re-written to keep pace with the ever-increasing literature of the subjects

The chapters on Affections of the Pharynx and Larynx are marked by reliable diagnostic rules and abundant directions for treatment, the writer not failing to express the results of his own experience. Some of the coloured plates of laryngeal diseases are exceedingly good and exactly represent the appearances seen in syphilis, tubercle, and carcinoma The chapter on Laryngeal Neuroses is also clear and useful, the subject being treated briefly, and only ascertained important facts are placed before the reader; much of the speculative theory so often written of in the numerous text-books on this subject is perhaps wisely omitted. All the affections of the nose commonly met with are thoroughly explained and their treatment is described. We think that hardly enough stress is laid on the difficulties of the after-treatment of nasal polypi in preventing return, and the association of these growths with sinus suppuration and necrosis is not prominently discussed. The illustration of a nasal polypus on p. 359 is also too highly coloured for clinical accuracy. The difficult subject of sinus suppuration might with advantage be amplified. We are all well aware that chronic discharges from the ethmoidal and sphenoidal regions are among the great difficulties of nasal surgery, and we should hail any advance in their treatment gladly. All these criticisms are, however, of a minor nature and do not detract from the value of the section on nasal diseases.

The section on Diseases of the Ear is eminently practical and marked by sound common sense and absence of recommendation of speculative methods of treatment. It is noteworthy to find that an authority in the position of Dr. McBride modestly explains his incapability of speaking with certainty on several debated points because of his want of experience. With regard to the radical operations on the mastoid in suppurations of the middle ear he remarks: "There are certain risks associated with the performance of all of them. ...... I do not think, however, that it is ever safe to be too sanguine as to the cure of the discharge, though this desirable result is often attained. In this respect the prognosis should be distinctly guarded." The author's views on the treatment of that common and inveterate cause of deafness—chronic aural catarrh—are eminently moderate and sensible and here, as throughout his work, no methods of treatment are advised that would not stand the test of clinical experience. This part of the book has some excellent coloured illustrations of diseased conditions of the membrane.

A critical digest is presented of intra-tympanic operations in chronic deafness with Eustachian obstruction, sclerosis, and adhesions. The writer points out forcibly their experimental nature. "The tendency of modern otologists—more particularly of the German school, who have in this respect been followed to some extent by American, French, and Italian authorities—is too much towards operations which are at best purely experimental. It would be no unfair criticism to state that, on perusing a chapter on this matter in any of the larger German works, the idea remains with the reader that otologists have vied one with another to cut out ever-increasing portions of the tympanic structures, that their reasons for so doing are not always sound, and that most credit is acquired by him who has succeeded in extracting most. It is true that the published cases are often said to be successful, and that we do not read of inflammatory reactions; but it is this very absence of inflammation in the recorded cases that makes one fear that, beyond those which have seen the light of day, there may be other instances of experimental operating which have been followed by less satisfactory results."

A prominent feature of this book is the abundance and nature of the local and general therapeutical remedies attached to each section. Another equally striking characteristic is the pronouncement of the author on the value of remedies, not from hearsay, but from his own experience.

As affections of the ear, nose, and throat are largely associated in practice, so this book must be exceedingly useful to practitioners, who will find in one volume an excellent practical account of these various maladies. The work is trustworthy throughout; errors of commission are practically not to be found, and those of omission are few. It cannot fail to enjoy the usefulness and deserved popularity of the preceding edition.

Treatment by Hypnotism and Suggestion, or Psycho-Therapeutics. By C. LLOYD TUCKEY, M.D. Aberd. Fourth edition, revised and enlarged. London: Baillière, Tindall, and Cox 1900 *Pp. 392. Price 7s. 6d.*

THE Treatment of Disease by Hypnotism and Suggestion continues to hold an irresistible attraction to the lay mind. By the practitioner of medicine, however, hypnotism is still regarded with some suspicion, but the opposition to its employment is not so great as it formerly was and it is generally believed that certain functional conditions can be favourably influenced by it. Even the most ardent supporters of psycho therapeutics, however, can scarcely claim that any great advance has been made, in this country at any rate, in the general adoption of hypnotism and suggestion as therapeutic measures, but if a physician select hypnotism as a method of treatment in certain functional disorders he can do so without fearing slight from his colleagues. As long as the treatment by these means is confined to functional affections no objection can be raised, but if it be claimed that all organic conditions can also be influenced then naturally serious opposition would be raised. In the work now before us Dr. C. Lloyd Tuckey treats the subject in an open and scientific measure He is evidently sincere in his belief in the efficacy of the measures which he recommends, and although we should take exception to some of his statements, yet as a whole there is much in the book that is interesting and instructive.

Much stress is naturally laid on the power of the mind over the body. We admit that certain symptoms may be brought about by expectant attention, that a rise of temperature may be the result of nervous excitement, that extreme anæmia may be caused by depressing emotions, but we are hardly prepared to admit that structural alterations can be so produced.

The methods of inducing the hypnotic state and the various phenomena produced are well described, and some points in the physiology and psychology of hypnotism are described in a thorough and interesting manner.

Considerable attention will naturally be directed to the accounts of cases which have been treated by hypnotism and suggestion by the author himself and by other observers. Most of these will be well understood as being especially applicable for this method of treatment, and they would be very likely to prove obstinate to the therapeutic measures in ordinary use, such as insomnia, neurasthenia, functional heart trouble, functional dysmenorrhœa, dipsomania, "mischievous morbid impulse," agorophobia, hysterical contracture of leg, hysterical aphonia, &c. With regard to some of the other cases, however, we admit we are sceptical. For instance, a case is recorded of a man who suffered from "syphilitic retinitis and optic neuritis." He was treated by mercurials, iodides, strychnine, electricity, but without avail, and his sight rapidly deteriorated. "In the left fundus there was a central scotoma and the right eye had lost the inner half of its field of vision. The right eye, which afterwards became the better of the two, appeared to be atrophic, its arteries were contracted to half their proper size, and the veins were also diminished in calibre." After 46 sittings we are told "there was very marked improvement . . . and it is evident that hypnotic suggestion was the curative agent." But we are not told the condition found in the fundi at the end of the treatment, and the weakness of the case is further emphasised by the passage—"In addition to being almost blind the patient, when he came under treatment, was affected with great mental depression and haunted by continual thoughts of suicide. He was also an excessive smoker." The removal of the mental symptoms and the desire for tobacco might be removed by hypnotic suggestion and the cessation of the excessive use of tobacco might account for the improvement in vision.

There are several cases that we might thus comment on. As we have already said, the majority of cases recorded are well chosen and demonstrate the uses to which hypnotic suggestion may be applied.

LIBRARY TABLE.

Original Contributions concerning the Glandular Structures appertaining to the Human Eye and its Appendages. With 71 Original Illustrations. By Adolf Alt, M.D., Professor of Ophthalmology in Beaumont Hospital Medical College, St. Louis. Published by the *American Journal of Ophthalmology*, St. Louis, Mo. 1900. 8vo. Pp. 23. Price $1.50, or 6*s.*—Although this is a very thin volume the drawings which it contains represent a considerable amount of work. The photographs, which were made by Professor Alt from his own sections, exhibit the appearances presented by sections of the orbital and palpebral lacrymal glands, the structures contained in the upper and lower lids as the Meibomian and acinous glands, the eyelashes and their sebaceous glands, and the sweat glands as seen both in horizontal and in vertical sections and in sections made parallel to the surface. In some points of view photographs are superior to drawings made by hand; they give relative size and position with an exactitude which is unattainable by the draughtsman, however expert he may be; on the other hand, there is a mistiness and a defect of clearness in the details that are disappointing and show that still much remains to be done in micro-photography. In the text that accompanies the plates the author gives the results of his dissections and mentions some interesting facts. He finds that the lacrymal gland is, as a rule, larger in the negro than in the Caucasian, sometimes even twice as large. The number of excretory ducts, as usually given in text-books (from 6 to 12), is, he thinks, exaggerated. Like Waldeyer, he has never observed a true lymph-follicle in the human conjunctiva; isolated acinous glands are, however, present both in the palpebral and ocular conjunctiva. Besides these he finds acino-tubular glands and others which he regards as modified sweat glands. The two lacrymal canaliculi he believes generally unite to form a single tube before discharging their contents into the lacrymal sac. Lastly, he has found a small spiculum or plate of hyaline cartilage in the tissue just below the lacrymal caruncle.

Manual of the Diseases of the Eye for Students and General Practitioners. With 243 Original Illustrations, including 12 Coloured Figures. By Charles H. May, M.D. Columbia University, New York. London: Baillière, Tindall, and Cox. 1900. Pp. 422. Crown 8vo. Price 8*s.* 6*d.* net.—Manuals of the size of the present volume upon ophthalmology are numerous and afford little field for originality. In all, the mode of examination of the eye by inspection, by subjective or functional methods, by objective examination with the ophthalmoscope, constitutes the subjects of the initial chapters. The diseases of the several structures, as of the lacrymal apparatus, orbit, conjunctiva, sclera, iris, chorioid, lens, and vitreous, usually follow and are succeeded by an account of glaucoma, the affections of the retina, errors of refraction, and disturbance of motility, and there is commonly a chapter on ocular therapeutics. This plan has been adopted in the present volume. The author does not pretend to give any original views on these subjects, but the accounts of the several affections are briefly and clearly given and supply just the details that a busy practitioner or a student dressing in the eye ward requires. The directions for the performance of the operations for ptosis, entropion, ectropion, enucleation, and evisceration of the globe, and for cataract extraction, which Dr. May thinks is now usually done without iridectomy, are concise and good. Dr. May seems to have fulfilled the object which he had in view—of saying enough but not too much. The illustrations are rather rough but are quite intelligible.

A Handbook of the Diseases of the Eye and their Treatment. By Henry R. Swanzy, A.M., M.B. Dub., F.R.C.S. Irel., Ophthalmic Surgeon to the Adelaide Hospital, Dublin. Seventh edition, with Illustrations. London: H. K. Lewis. 1900. Pp. 633. Price 12*s.* 6*d.*—When a manual for students has reached its seventh edition it may be considered to have passed successfully through its period of probation and to have proved its utility to those for whom it was intended. And, indeed, Dr. Swanzy's treatise is a very well-arranged manual. It owes its success to the clearness with which it is written, the care the author has taken to avoid unnecessary detail, the reliance that may be placed on the accuracy of the account given of each disease, and on the judicious treatment recommended, due to the fact, not only that Dr. Swanzy has had large opportunities of comparing different methods of therapeutic and operative procedure in the important hospitals with which he is connected, but that he possesses great powers of observation and a retentive memory. The subject of refraction, so difficult to give briefly, occupies a reasonable space, only those facts being given which it is imperative that every ophthalmic student should know. In regard to light perception, which is too rarely tested, Dr. Swanzy regards the photometer of Dr. Wallace Henry of Leicester as the best, in which a standard light is gradually revealed by the removal of successive plates of opal glass. The author considers at some length both in the text and in an appendix the method employed by Professor Hering for determining the colour sense. Recent ophthalmological work has been carefully studied. Thus we find that Dr. Bleuler's recommendation of applying cocaine ointment made with lanoline in the proportion of 1 per cent. is mentioned as affording great relief to pain in cases of herpes zoster ophthalmicus. Dr. Mules's operation for ptosis is also given in full, as is an account of the remarkable affection of which numerous histories have been collected by Dr. StClair Thomson—optic neuritis associated with persistent dropping of watery fluid from the nostril, which fluid is believed to be of cerebrospinal origin. In regard to cataract Dr. Swanzy seems to prefer the three-millimetre flap operation with iridectomy, first proposed by de Wecker, and he describes the proceedings to be adopted with great minuteness of detail. The application of the Roentgen rays for the discovery of foreign bodies, such as chips of metal in the eye, is fully described, and the text is illustrated by several drawings showing the mode of employment of the apparatus devised by Mr. Mackenzie Davidson for this purpose. When once the position of the chip is known with an approach to accuracy the introduction of a magnet will sometimes effect the capture and will enable it to be withdrawn without much injury to the vitreous. The book will be found very useful both by the student and the practitioner, and contains all that is requisite to guide them to the right diagnosis and treatment of the principal diseases of the eye.

The Frog: an Introduction to Anatomy, Histology, and Embryology. By the late A. MILNES MARSHALL, M.D., D.Sc., M.A., F.R.S., Professor in the Victoria University, Manchester. Edited by G. HERBERT FOWLER, B.A., Ph.D., late Assistant Professor of Zoology, University College, London Seventh edition, revised and illustrated. London: David Nutt. 1900. Pp. 168. Price 4*s*.—The first edition of this work was published in 1882 and various minor alterations prompted by the inquiries of students or found advantageous in its use as a manual of dissection were made by the author in successive editions until his recent lamented death. The work has been placed in the hands of Dr. Fowler who states in the preface that he has not found it requisite to make any substantial alteration either in the substance or in the arrangement of the treatise. After a short introductory chapter on the use of the microscope and the mode of examining preparations the several chapters are devoted to the general anatomy of the frog: the digestive, vascular, osseous, muscular, and nervous systems, the eye and ear, the reproductive system, and the development of the animal. The most important addition consists in the introduction of a new set of woodcuts, drawn by Miss Mabel Green, in illustration of the process of development and metamorphosis. These are very well done and reflect credit on her accuracy and skill.

FEES FOR LUNACY CERTIFICATES.—At the meeting of the Devonport Board of Guardians held on Oct. 26th it was stated that letters had been sent to 25 medical practitioners asking whether they would accept half a guinea as the fee for the examination of pauper lunatics. 18 replies had been received. Six medical men agreed to accept the fee, 10 were against doing so, and two declined to express an opinion. After some discussion the guardians resolved to write to the bench of magistrates asking them to appoint one of the six medical practitioners to examine supposed cases of insanity in paupers.

THE LANCET LABORATORY.

VARIOUS CANADIAN WINES.

(J. S. HAMILTON AND CO., BRANTFORD, ONTARIO, CANADA. AGENTS J. AND W. J. COURTNEY, 14, TOOLEY-STREET, LONDON, S.E.)

CANADIAN wines are not very well known in this country and the analysis of some specimens which we have recently received should therefore be of interest. The varieties of wines produced comprise dry and sweet white wines, sparkling and still, and red wines. As might be conjectured it is usually the practice where wine is produced to obtain spirits also and grape brandy is amongst the other products of viticulture in Canada. We have examined four distinct specimens of Canadian wine and the results were as follows:—Medoc (Chateau Pelee): extractives, 3 57 per cent.; mineral matter, 0 15 per cent.; alcohol, by weight 10 69 per cent., by volume 13 24 per cent., equal to proof spirit 23 21 per cent.; volatile acids reckoned as acetic acid, 0 276 per cent.; fixed acids reckoned as tartaric acid, 0 277 per cent.; and sugar, 0·51 per cent. This is a red wine simulating the wine of the Medoc district. We do not doubt that it is a perfectly pure wine, but, as will be seen from the analysis, it is somewhat acid in character and the somewhat sour taste confirms this result Some amount of acetification had set in, otherwise the flavour was delicately fruity, suggesting muscatel grape. Dry Catawba: extractives 2 29 per cent.; mineral matter, 0 115 per cent.; alcohol, by weight 12·38 per cent., by volume 15 30 per cent., equal to proof spirit 26·82 per cent.; volatile acids reckoned as acetic acid, 0·198 per cent.; fixed acids reckoned as tartaric acid, 0·48 per cent.; and sugar, 0 35 per cent. This is a dry wine resembling Sauterne. It is clean on the palate and sound. As will be seen it contains a very small amount of sugar and is therefore correctly described as dry. St. Augustine: extractives, 12 19 per cent.; mineral matter, 0 11 per cent.; alcohol, by weight 13 92 per cent., by volume 17·17 per cent., equal to proof spirit 30 09 per cent.; volatile acids reckoned as acetic acid, 0 132 per cent.; fixed acids reckoned as tartaric acid, 0·247 per cent.; and sugar, 11·40 per cent. This is a red wine possessing the style of port. It is quite sweet as the figures of analysis will convey. It is a pure, sound wine with good fruity taste. It is intended chiefly for sacramental purposes. L'Empéreur: extractives, 4 675 per cent.; mineral matter, 0·105 per cent.; alcohol, by weight 11 54 per cent, by volume 14·27 per cent., equal to proof spirit 25 01 per cent.; volatile acids reckoned as acetic acid, 0 168 per cent.; fixed acids reckoned as tartaric acid, 0 48 per cent.; and sugar, 3 24 per cent. This is Canadian champagne and it is a very good wine. Though described as dry it contains a little over 3 per cent. of sugar, but it is not excessively sweet to the taste. There is no evidence to show in these results that the wines are not the normal and genuine products of fermented grape-juice. Doubtless, as further experience is gained in the methods of cultivation of the grape and of the rearing of the wine which it yields even better results will be attained. As it is, they are already encouraging

SPIRITINE.

(SPIRITINE, LIMITED, 5, CARTERET STREET, LONDON, S.W.)

Spiritine is described as a solidified spirit. We doubt whether, strictly speaking, that is the case. It is a waxy-looking substance, coloured blue, contained in tins provided with a screw-down lid. It burns on applying a light just as ordinary spirit burns. The device is most ingenious and most convenient. It is quite safe to use and may be carried about fact furnishes a very good answer to the question, What about other professional witnesses? The members of no other profession are called upon to give evidence so often as are those of the medical profession—had they been so required in all probability the fees would have been increased long ago. It is only among that profession the duty of whose members it is to give death certificates without fee and who work gratuitously among the poor that the injustice of being compelled to suffer pecuniary loss would so long have been endured.

Nothing of permanent value can be done till Parliament meets for the despatch of business, which may not be till next year, but meanwhile much may be done towards effecting a reform if all those members of the profession who have been compelled to be medical witnesses at a pecuniary loss will submit their cases in detail to their Parliamentary representatives.

A NEW epoch in the history of Greater London is marked by the founding of the metropolitan boroughs beyond the boundaries of the ancient City of London. Important and powerful corporations are to replace vestries, and for the first time many of the people of London have been called upon to decide what manner of men shall represent them in the management of their important municipal affairs. We fear that many, perhaps the majority, of those most capable of forming a just opinion of the contending candidates, have yielded to the feeling that they have had enough of elections for the present and have allowed themselves to believe that they had neither leisure nor opportunity to inquire as to the respective merits of persons of whom in many instances they have heard for the first time this week. They have said that they have little to complain about. They have allowed that the streets are not kept as clean as are those in the City, that snow is allowed to lie about them too long, and that their lighting leaves something to be desired; but their view has been that things might be worse and that it is a good thing that anyone can be found to be a member of a borough council. Such a typical citizen, while saying that he for his part would not serve on a council, may add that it is best that he should not vote, because as likely as not he would vote for the wrong man. So he is willing to leave the election to those who know. Thus, to use the expression of the Bishop of ROCHESTER, the casual man is inclined "to let apathy overcome him." This is a most unsatisfactory state of things, which has arisen from the huge size of London and the arbitrary manner in which its domestic affairs have been delegated to a large quantity of little vestries. And this is the state of things which every medical man will rejoice to see ended by the behaviour of the new municipal government.

Lord ROSEBERY in an address delivered on Friday, Oct. 26th to the Christian Social Union gave some very good advice as to the approaching elections. Some of his remarks were so obviously true that they appeared trite, but it is a commonplace of life that it is the obvious which most often escapes notice, and a loss of perception of the relative importance of events is often shared by a vast majority of a great nation. "Our interests are not all in South Africa," said Lord ROSEBERY, "and the inhabitants of this great metropolis should remember that not all their interests are locked up 6000 miles from home," a truism not universally appreciated at the present moment. Lord ROSEBERY pointed out the great good that might follow upon the revolution in the municipal management of London, and although the beatitude of the millenium is not to be expected from the deliberations of the borough councils, we agree with his lordship, who speaks not only as a wise man but also with the special authority of an ex-chairman of the London County Council. London has outgrown vestries, and the new duties of the borough councils will be by no means trivial. The men who should be selected to sit on them should be those who come forward, not to serve themselves but the public interest. They should not wish to use the Council as a preliminary debating society through which to pass on their way to St. Stephen's They should be uncorrupted and incorruptible. They should not be chosen by the political label they may choose to adopt; they should be men whose only interest is that of their constituencies. They should be men of business. A fair proportion of the recent candidates seem to have fallen under this category. There are two classes of persons, who, according to Lord ROSEBERY, are *primâ facie* likely to be undesirable borough councillors. Builders and owners of property are, he thinks, open to suspicion. Of the builder he would ask where and what he has built and of the owner where is his property. The list, we think, might be extended. Why, for example, should not publicans and public-house proprietors be included in it? What should be said of owners of factories which poison the air with foul smoke? But the question of the housing of the poor is evidently the one which Lord ROSEBERY has at present most at heart, and the medical bearings of this question in its relation to public health make it one of the first interest to medical men.

The people of London have been scandalously neglected up to the present time by their representatives on the vestries, and no one can be reckoned a satisfactory councillor of the new boroughs who does not use his every endeavour to obtain for London:—

1. Cleanliness in the streets.

2 Purity of the air—so far as this can be done under the provisions of the present law.

3 A constant and pure supply of water—so far as it can be obtained under the present enactments.

There are those who look upon dirt in the streets as the normal state in winter, who like fog, and who are indifferent concerning the water that they drink. Such men should not be councillors. The streets in the City of London are washed every night. There is no reason why the streets in the new boroughs should not be washed. No one should be elected to the new councils who is not in favour of clean streets. The air of London is poisoned by the smoke from numerous factories, restaurants, and electric-light stations. The Public Health (London) Act, 1891, makes ample provision for prosecution in cases in which the air is polluted by smoke. The vestries have generally neglected their duties in protecting the people against this unwholesome nuisance. Every councillor should be as active as his predecessors have been supine. The metropolitan water companies are under a statutory obligation to supply the necessary amount of water at a moderate price. The laws in force for the protection of the people against the exactions and negligence of the companies are, as readers of THE LANCET know, numerous and complex. The vestries, generally speaking, have entirely neglected even to attempt to protect the numerous individuals who have suffered from the defaults of the water companies. This must be altered by the new borough councils, which should be strenuous in securing for the water consumers of their boroughs the benefits which it is the duty and the privilege of the metropolitan water companies to afford.

"Ne quid nimis."

NORTH OF IRELAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

THE opening meeting of the session of 1900-1901 of the North of Ireland Branch of the British Medical Association was held in the Museum, Belfast, upon the appropriate date of the festival of St. Luke (Oct. 18th). The chair was occupied by the President of the branch, Professor Byers, who delivered his opening address. After a few introductory remarks Professor Byers went on to say that he thought the present occasion to be an admirable one upon which to attempt to answer the question, "How has the science and art of medicine in its various departments been influenced by the wonderful discoveries of this century, which dazzle us not merely by their ingenuity and by the rapidity with which they have followed one another, but still more by their practical application in this most utilitarian age to the diagnosis, prevention, and treatment of disease?" Bacteriology and the new science of hæmopathology had opened up a new and most promising field for original investigation. Instances were then given of the results obtained by investigation of the blood, such as the differential diagnosis between malaria and typhoid fever, the value of "vaccination" against typhoid fever, and of the administration of calcium chloride in hæmorrhages or of alkalies in scurvy. The early cases of plague in Glasgow had been verified by an examination of the blood and thus preventive measures were at once taken, with what success they were all aware. Professor Byers concluded this portion of his address with an appeal for State endowment of research laboratories. He then went on to speak of the British Medical Association, pointing out how it had originated as a provincial society formed as a protest against the tendency to locate medical organisations too much in the metropolis. With regard to the scientific work of the Association, that had been well carried out, except that the amount given as grants in aid of scientific research was ridiculously small. He himself had been able to bring about an alteration in the composition of the Scientific Grants Committee which would, he hoped, in the near future result in these grants being more widely diffused. As regards the work of the Association for the maintenance of the honour and interests of the medical profession it was evident that the members of the profession thought that the Association had not done enough in this direction. Hence the multiplication of defence societies and the like, which multiplication resulted in loss of money and in a waste of machinery. Surely it would be better to have one great national medical association. The British Medical Association must consider in the future more than it had done in the past the honour and interests of the profession. Professor Byers then referred to the Reorganisation Committee which was appointed at Ipswich and made an interesting prophecy as to the questions which would probably be submitted to the branches in the provisional report of that committee. The branches would probably be asked to discuss the constitution of the Council, the best means of obtaining a thorough representation of all the members of the Association, medical defence, machinery for watching legislation so far as it affected medical interests, a professional information bureau, and the establishment of a benevolent fund. Organisation and union were what the profession needed most. Professor Byers's able address raised two points which are doubtless most important. With regard to the matter of State aid for scientific research we fear that those who look for it look for a chimæra. Compared with foreign Governments the British Government does nothing to help science. Private benevolence is good and has done wonders from the days of Rahere down to the foundation of the Thompson Yates laboratories at Liverpool, but in matters in which the public health is concerned we think that private benevolence should be supplemented by State aid. With regard to the more personal matter of union in the medical profession the cure for the present distress rests with the members of the profession themselves. How great, as Professor Byers pointed out, would be the influence upon a Government department of a solid demand from the members of the British Medical Association. Everyone knows the trite saying, "Union is strength," but how few medical men really set themselves to realise such union as might be realised—one which if used rightly would have incalculable power for good, not merely in purely medical matters, but in such great questions as the housing of the poor, a pure water-supply, the adulteration of food, and the purifying of the atmosphere of our great towns.

PLUMBERS' WORK IN RELATION TO PUBLIC HEALTH.

AMONG a steadily increasing section of the medical profession who take more than a general interest in the important question of plumbers' work Dr. S I. Mansel-Howe occupies a prominent place. Dr. Mansel-Howe has original notions, and original notions, if not always acceptable, are generally interesting. This is perhaps the case in relation to some of the suggestions made in a lecture delivered by him at the Town-hall, Maidstone, under the presidency of the Mayor, last spring, and recently printed in pamphlet form.[1] Mingled with much excellent advice upon the sanitary arrangements of our dwellings is an important departure from the commonly accepted system of procedure which is, unless in the case of terrace houses, unlikely to meet with general acceptance. The distribution of gully traps at the ground level, admittedly a weak point in all systems of drainage, owing to the accumulations of refuse which they frequently retain, is one of his principal objections. Of course, the object of these gullies is to cut off all sink wastes and rain-water pipes from immediate connexion with the house drain. Dr Mansel-Howe's proposal virtually amounts to re-connecting these pipes, placing them in the same relationship to the house-drain, through the medium of a disconnecting chamber, as the house-drain bears to the public sewer. Such a plan would involve in many instances almost a double system of drains and manholes, with an accompanying increased percentage of risk for the escape of drain air. This, apart from its economic aspect, seems a questionable advantage. Briefly, he proposes to carry separate drains from the several rain-water pipes, sinks, and bath-wastes into a chamber formed fact furnishes a very good answer to the question, What about other professional witnesses? The members of no other profession are called upon to give evidence so often as are those of the medical profession—had they been so required in all probability the fees would have been increased long ago. It is only among that profession the duty of whose members it is to give death certificates without fee and who work gratuitously among the poor that the injustice of being compelled to suffer pecuniary loss would so long have been endured.

NORTH OF IRELAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

THE opening meeting of the session of 1900-1901 of the North of Ireland Branch of the British Medical Association was held in the Museum, Belfast, upon the appropriate date of the festival of St. Luke (Oct. 18th). The chair was occupied by the President of the branch, Professor Byers, who delivered his opening address. After a few introductory remarks Professor Byers went on to say that he thought the present occasion to be an admirable one upon which to attempt to answer the question, "How has the science and art of medicine in its various departments been influenced by the wonderful discoveries of this century, which dazzle us not merely by their ingenuity and by the rapidity with which they have followed one another, but still more by their practical application in this most utilitarian age to the diagnosis, prevention, and treatment of disease?" Bacteriology and the new science of hæmopathology had opened up a new and most promising field for original investigation Instances were then given of the results obtained by investigation of the blood, such as the differential diagnosis between malaria and typhoid fever, the value of "vaccination" against typhoid fever, and of the administration of calcium chloride in hæmorrhages or of alkalies in scurvy. The early cases of plague in Glasgow had been verified by an examination of the blood and thus preventive measures were at once taken, with what success they were all aware. Professor Byers concluded this portion of his address with an appeal for State endowment of research laboratories. He then went on to speak of the British Medical Association, pointing out how it had originated as a provincial society formed as a protest against the tendency to locate medical organisations too much in the metropolis. With regard to the scientific work of the Association, that had been well carried out, except that the amount given as grants in aid of scientific research was ridiculously small. He himself had been able to bring about an alteration in the composition of the Scientific Grants Committee which would, he hoped, in the near future result in these grants being more widely diffused. As regards the work of the Association for the maintenance of the honour and interests of the medical profession it was evident that the members of the profession thought that the Association had not done enough in this direction. Hence the multiplication of defence societies and the like, which multiplication resulted in loss of money and in a waste of machinery. Surely it would be better to have one great national medical association. The British Medical Association must consider in the future more than it had done in the past the honour and interests of the profession. Professor Byers then referred to the Reorganisation Committee which was appointed at Ipswich and made an interesting prophecy as to the questions which would probably be submitted to the branches in the provisional report of that committee. The branches would probably be asked to discuss the constitution of the Council, the best means of obtaining a thorough representation of all the members of the Association, medical defence, machinery for watching legislation so far as it affected medical interests, a professional information bureau, and the establishment of a benevolent fund. Organisation and union were what the profession needed most. Professor Byers's able address raised two points which are doubtless most important. With regard to the matter of State aid for scientific research we fear that those who look for it look for a chimæra. Compared with foreign Governments the British Government does nothing to help science. Private benevolence is good and has done wonders from the days of Rahere down to the foundation of the Thompson Yates laboratories at Liverpool, but in matters in which the public health is concerned we think that private benevolence should be supplemented by State aid. With regard to the more personal matter of union in the medical profession the cure for the present distress rests with the members of the profession themselves How great, as Professor Byers pointed out, would be the influence upon a Government department of a solid demand from the members of the British Medical Association. Everyone knows the trite saying, "Union is strength," but how few medical men really set themselves to realise such union as might be realised—one which if used rightly would have incalculable power for good, not merely in purely medical matters, but in such great questions as the housing of the poor, a pure water-supply, the adulteration of food, and the purifying of the atmosphere of our great towns.

PLUMBERS' WORK IN RELATION TO PUBLIC HEALTH.

AMONG a steadily increasing section of the medical profession who take more than a general interest in the important question of plumbers' work Dr. S I. Mansel-Howe occupies a prominent place. Dr. Mansel-Howe has original notions, and original notions, if not always acceptable, are generally interesting This is perhaps the case in relation to some of the suggestions made in a lecture delivered by him at the Town hall, Maidstone, under the presidency of the Mayor, last spring, and recently printed in pamphlet form.[1] Mingled with much excellent advice upon the sanitary arrangements of our dwellings is an important departure from the commonly accepted system of procedure which is, unless in the case of terrace houses, unlikely to meet with general acceptance. The distribution of gully traps at the ground level, admittedly a weak point in all systems of drainage, owing to the accumulations of refuse which they frequently retain, is one of his principal objections. Of course, the object of these gullies is to cut off all sink wastes and rain-water pipes from immediate connexion with the house drain. Dr. Mansel-Howe's proposal virtually amounts to re-connecting these pipes, placing them in the same relationship to the house-drain, through the medium of a disconnecting chamber, as the house-drain bears to the public sewer. Such a plan would involve in many instances almost a double system of drains and manholes, with an accompanying increased percentage of risk for the escape of drain air. This, apart from its economic aspect, seems a questionable advantage. Briefly, he proposes to carry separate drains from the several rain water pipes, sinks, and bath-wastes into a chamber formed in the upper part of either the inspection chamber at the upper end of the house-drain or of the disconnecting chamber at the lower end of the house drain. Thus, the usual chamber is formed but is provided with a false floor placed a short distance above the bottom of the manhole and fitted with an air tight cover to give access to the lower chamber. In this floor all the gullies are to be placed, each having a short connexion into the channel of the lower chamber. The upper chamber is ventilated by means of a three-inch anti-syphonage pipe which is carried up above the roof and which is common to all the sink and lavatory fittings, always excepting the urinal or slop sink; also, of course, it is ventilated by the several waste-pipes discharging into this chamber. It is not very clear how it is proposed to prevent the air from the gully-chamber escaping up the rain-water pipes and discharging near windows at low levels, but this has doubtless been provided for in the scheme. The lower chamber is ventilated by the soil-pipe and by the soil-pipe anti-syphonage pipe which Dr. Mansel-Howe proposes should be carried down for this purpose. He entertains a strong dislike to all puff-pipes from sinks and valve-boxes being discharged anywhere below the roof level. He also objects, and with good reason, to the so called "fresh-air inlets" so frequently met with in such unsuitable positions in our crowded thoroughfares. These, he maintains, should always be carried up above the roof level. Dr. Mansel-Howe's scheme has been well thought out and should receive the consideration of those interested in the advance of sanitary work.

A CASE OF FAMILY PERIODIC PARALYSIS.

THE disease known as "family periodic paralysis" is a very rare and striking condition and while in all only four instances have been published only three of them strictly conform to the conditions necessary—viz, periodicity, occurrence in more than one member of a family, and associated spinal paralysis. Dr. Leo M. Crafts, professor of nervous diseases in the Hamline University, Minneapolis, U S A., records the following interesting case in the *American Journal of the Medical Sciences* for June A young man, aged 37 years, a commercial traveller, with large hands and feet and an awkward waddling gait suggestive of the early stage of pseudo-muscular hypertrophy, active and energetic, has been under observation at intervals for about seven years His physical development is remarkable. "The lower legs, the hips, and the thighs are abnormally large, strikingly like those of pseudo-muscular hypertrophy, and the lumbar curve is emphasised. The arms, too, are moderately heavy, but the muscular strength does not correspond at all to the development, and while it is not weak it is distinctly less than normal and he has comparatively little power of endurance." His height is five feet five inches and his weight is 140 lb The calves measure 15¼ inches, the thighs 19¼ inches, and the forearms and upper arms 11 inches each. The superficial veins in both upper and lower extremities are very large and prominent. The family history is distinctly neuropathic. The father was a heavy drinker, the mother was of frail health, one aunt was markedly eccentric, and two or more ancestors had died from "paralysis" The patient himself at the age of 12 years was suddenly attacked with illness one morning in bed and was unable to get out, being only able to move his arms and legs slightly and with great difficulty. He improved in a few days, but had a recurrence six months later, and other attacks since then at varying intervals. A year after the first attack he had a severer attack and three years later another serious attack. His last serious attack, the worst of all, occurred three years ago following extreme exertion. He suffered from great exhaustion and muscular feebleness and also from constant vomiting, fluid in character and charged with bile. He became pale, sallow, and collapsed, with small rapid pulse and great prostration which lasted three days, after which he recovered. The attacks had recurred periodically and were as a rule preceded by constipation. A frequent immediate cause was over exertion, either prolonged or short and sharp, as, e g., running to catch a train while carrying heavy bags. "Indiscretions in diet seemed to have a direct bearing on the occurrence of the condition and he has learned to avoid certain foods, such as rich pastry, sweet preserves, and cheese." The onset of an attack was always gradual, usually beginning simultaneously in the hands and feet. Over-exertion while an attack was subsiding generally caused recurrence or altered a partial seizure to a complete one. The muscles of the limbs and body felt soft and flaccid and entirely relaxed in an attack; the chest-wall hardly moved and respiration seemed entirely confined to movements of the diaphragm. The blood showed marked lymphocytosis, and analysis of the fæces yielded a toxic substance which produced in rabbits a paralysis lasting 48 hours. Bernhardt regarded the affection as allied to the dystrophies, but its exact pathology is as yet obscure, though Dr. Crafts's observations confirm its toxic nature.

THE TERM "INFLAMMATION."

DR ANDREW H. SMITH of New York recently published in the Transactions of the Association of American Physicians a most interesting and in some respects original paper bearing on the above subject. Dr. Smith holds views almost identical with those expressed by Dr. J. F. Payne at the meeting of the British Medical Association in 1898 with regard to the anomaly of the term "inflammation" as used now—that is, when the fact of the remarkable advance made in pathology is taken into consideration. Dr. Smith, however, is more bold in setting forth his opinions and in addition suggests a remedy. He points out that of the four cardinal symptoms which were originally held to constitute the conditions known by the name of inflammation only one is still insisted upon to identify the inflammatory process—namely, swelling. He shows that by doing away with all but this one test the difficulty of defining the term is immensely increased, and further insists that the difficulty is inevitable so long as we insist upon the idea that a new action is set up by some exciting cause and that once initiated this new action goes on independently and works out results due to itself After describing the action of inflammation as it appears to him Dr. Smith claims that the termination "itis" should be dropped for the reason that most of the phenomena heretofore included under the term "inflammation" are manifestations of the local action excited by a micro-organism or by a poison circulating in the blood. Such action should be expressed by a termination to be affixed to the name of the organism or poison, if the same be determined, or to the organ or part affected in case the particular infecting organism or poison be not identified. Attention is drawn to the fact that we have a universally accepted precedent in the case of tuberculosis, and Dr. Smith is of the opinion that if a general name is demanded as a substitute for inflammation no one word ought to be made to include all the heterogeneous unrelated processes and conditions which have been comprised under that term. At least three words would be required to express different kinds of *noxæ* acting in different ways and leading to essentially different results. These, he thinks, might be "traumosis" to include wounds and injuries, "toxosis" to include the local action of poisons in the blood, and "bacteriosis" to include the action of micro-organisms. The *New York Medical Record* of Oct. 6th has a highly eulogistic article, upon Dr. Smith's suggested radical innovations in medical and surgical phraseology, but is inclined to think that the medical profession is too tightly bound by custom and routine to be easily persuaded that the benefits to be derived from the proposed changes will outweigh the disadvantages and trouble consequent upon such changes. The *New York Medical Record*, however, truly says that Dr. Smith's courageous arraignment of the inappositeness of the term inflammation, as used now is, a valuable contribution to latter-day scientific literature, which should embolden those less fearless to follow his sagacious lead into this interesting field of inquiry. The most valuable outcome from the propagation of the view that inflammation is in no proper sense a new force, an enemy projected into the arena, a disturbing influence to be dreaded, a disease to be "treated" will be that its treatment will be abandoned. The cause of the true malady will be sought for, and when found attacked. The direction of modern therapeutics, too, tends towards the method of not treating the disease so much as the patient in acute infectious diseases. If Dr. Smith's conclusions and the conclusions of those who have written to the same end but have not stated the case so strongly are accepted their communications will serve a most beneficial purpose and should pave the way to a more enlightened therapy Since the latter is the very essence of the physician's life-work, the importance of the theme cannot be over-estimated.

BLACKWATER FEVER.

IN the *Deutsche Medicinische Wochenschrift* of Oct 4th Dr. Hans Ziemann of the German navy gives some account of the views to which he has been led by his experience of blackwater fever at Cameroon, West Africa. He has never found any specific exciting cause for the disease. He considers that in some very unhealthy malaria districts a predisposition to blackwater fever becomes established in a certain number of persons, and that in general this predisposition increases with the number of attacks of malaria which the patients have; but, on the other hand, it may diminish if some power of resistance to malaria is attained. This predisposition may affect the most robust members of quite healthy families, but it is more apt to occur in persons in whom the hæmorrhagic diathesis may be suspected and in those who live under depressing conditions of mind or body It seems to arise most readily in persons who have been infected with the minute parasites of tropical or æstivo autumnal fever. The predilection of blackwater fever for certain districts may be owing to local conditions increasing the virulence of the parasites, their essential characteristics being otherwise unchanged. In Cameroon, where blackwater fever is so dangerous, only a few sexual parasitic forms, such as crescents, are to be found in the blood. In Italy, on the other hand, these forms are of very frequent occurrence and are most abundant in cases having a tendency to recover. In Cameroon there is often a great disproportion between the clinical symptoms and the number of parasites in the peripheral blood, but in Italy, where blackwater fever is extremely rare, although infection with parasites closely allied to those of tropical fever is very common, Dr. Ziemann seldom met with this disproportion. Predisposition being assumed in all cases as already mentioned, all the conditions under which blackwater fever arises may be reduced to four—namely, (1) in the course of an attack of malaria without quinine having been given, but this is rare; (2) in the course of an attack of malaria treated with quinine, this being by far the most common condition; (3) in patients who have recovered from malaria and have no parasites in their peripheral blood but are nevertheless taking quinine; and (4) in patients who have recovered from malaria and blackwater fever and have no parasites in their peripheral blood and are not taking quinine, this condition being rare. Dr. Ziemann, therefore, recognises no distinction between the so-called quinine hæmoglobinuria and hæmoglobinuric malarial fever. Blackwater fever occurs also among the Togos negroes who have never taken quinine, and the same thing has been observed on the Congo. Dr. Ziemann has recorded a unique case in which tropical fever was diagnosed microscopically, and in this patient hæmoglobinuria was brought on by 0 01 gramme (one-sixth of a grain) of quinine. On the west coast of Africa it is by no means uncommon for from 0 1 gramme to 0 25 gramme (from one and a half grains to four grains) of quinine to produce hæmoglobinuria in predisposed persons suffering from malaria, so it is evident that in that district quinine should be administered with caution. Dr. Ziemann has found benefit from injections (Infusionen) of physiological salt solution in anuria and from chloroform solutions given by the mouth in obstinate vomiting.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH AND THE DIAGNOSIS AND TREATMENT OF PLAGUE.

WE are informed by the editor of *Public Health* that the Council of the Incorporated Society of Medical Officers of Health have arranged for a lecture and demonstration upon Plague to be given on Saturday next, Nov. 10th. Mr. Cantlie has accepted the task of dealing with the etiological and clinical parts of the subject and Dr. E. Klein will undertake the bacteriology. Dr. A. K. Chalmers will describe the suitable preventive measures, more especially with regard to the line followed at Glasgow. The meeting for this purpose is fixed for 2 30 P M on Saturday next, the day following the ordinary meeting of the society, and will be held at the Examination Hall of the Conjoint Colleges, Thames Embankment. The meeting will be open to the whole profession, but admission will be by ticket, application for which is to be made to the honorary secretaries, 197, High Holborn, W.C.

INFECTION THROUGH A MANGLE.

DR. JOSEPH PRIESTLEY, the medical officer of health of Lambeth, presented to his vestry on Oct. 25th a most interesting report upon an outbreak of typhoid fever in the parish due to infected mangles. The incidence of the disease was practically limited to three streets covering an area of half a square furlong and containing 124 houses at rents varying from 10*s.* to 14*s.* a week. There were in all 41 cases occurring in 24 houses, and 16 of the patients were males, while 25 were females. The first case was notified on Sept. 7th There was much inter-communication between persons and families living in different houses, but the most important means of inter-communication was found to be in connexion with the mangling of clothes. Many of the inhabitants of the area after washing their clothes in their own homes took them to some neighbour to be mangled Owing to this custom bedding often stained with urine and fæces from typhoid fever patients were mixed together with, and mangled in the same machine as, bedding from non-infected houses. Thus the disease was spread. Four definitely infected mangles were traced and these four were responsible for 26 cases of typhoid fever. On August 14th a child, aged two years, sickened and was treated as suffering from infantile diarrhœa. The clothes from this house were washed and then sent to a house where there was a mangle—namely, 14, S—— Place—in which house there was also a case of unrecognised typhoid fever which was not diagnosed until about three weeks had passed 12 cases of typhoid fever were directly traced to this infected house. Nine infected houses gave rise to 17 secondary cases due to infection from previous patients before such patients were removed to the hospital. Undiagnosed cases were also responsible for the spread of the disease. Thus, one child living in F—— Street whose case was unrecognised for a space of 26 days infected directly three other persons who in their turn infected nine more. One case presumably arose from the eating of ice-cream. Dr. Priestley lays special stress upon the paramount need for early diagnosis. Bacteriological examination is supplied free of cost by the vestry and is being more and more used. Early removal to hospital is also imperative, there being no means of home isolation in the neighbourhood.

URETERAL ANASTOMOSIS.

IN the *Journal of the American Medical Association* of Oct. 6th is published an important paper on this subject which was read at the recent meeting of the American Medical Association by Dr. Howard Kelly of Baltimore. Under the subject are included two operations—uretero-ureterostomy (in which a piece of ureter is sacrificed and the ends are brought together) and uretero-cystostomy (in which the vesical end of the ureter is sacrificed and the upper end is anastomosed to the bladder). A ureteral anastomosis is as difficult an operation as can be performed, fully as delicate as any eye operation. It is usually required for accidental injuries of the ureter during operations, usually of the pelvic portion—a fact of importance for successful anastomosis. The ureter may be cut in mistake for a blood-vessel or torn out of the pelvis with an adherent ovarian cyst, myoma, pyosalpinx, or similar condition. It is voluntarily sacrificed when it passes through a carcinomatous mass in the broad ligament. Before performing the difficult operation of anastomosis it is important to make sure that the ureter is performing its function, for occasionally the disease which necessitates the pelvic operation has occluded the ureter and led to abolition of its function. The success of an anastomotic operation depends on accurate union without injury of the delicate ureteral structures, which is rendered difficult by their flaccidity and sometimes by difference of calibre. To overcome these difficulties Dr. Kelly has constructed a ureteral guide which looks like a little hammer with the handle attached at an angle and flush with one end. The head or guiding part is four centimetres long and rounded at the free end. Near the end is a groove in which to tie the ureter in order to fix it during anastomosis. The following instruments are needed: delicate ureteral tissue forceps, fine scissors, a tiny round curved needle with the eye open at the end, and delicate needle-forceps. The operation is performed thus: a fine silk mattress-suture is passed through the under surfaces of the cut ends and tied, bringing them accurately together. A longitudinal slit is made in the upper end of the ureter two centimetres distant from the extremity just large enough to admit the guide easily. The rounded end of the guide is pushed through the slit into the ureter down through the open end and well into the lower end, where it is loosely tied in the groove. Fine silk sutures, interrupted or mattress, are passed at intervals of from one to one and a half millimetres through all the coats except the mucosa. During the suturing the ureter can be rotated from side to side by moving the handle of the guide. At the completion the ligature tied around the guide is cut and the guide is withdrawn. The success of the suturing may now be tested by injecting water through the slit and seeing it flow freely towards the bladder without leakage. The slit is readily closed by three or four fine mattress sutures of silk. Dr. Kelly has the guides made in three sizes. When there is a marked difference in calibre between the upper and lower portions of the ureter he uses a large size to dilate the smaller end and to facilitate approximation. A surgeon who would rarely have to do this operation and has not the "guides" can easily extemporise one by cutting a piece of wood to the desired shape, fixing a thread or a long needle in one end, and sterilising this makeshift. Uretero-cystostomy is similarly performed. A slit is made in the peritoneal surface of the bladder, the guide slipped in, the right or left vesical cornu pushed out in the direction of the divided urethral end, and an opening made at the nearest point just enough to admit the ureter. The guide is then slipped into the ureter and tied, and the ureter with its lower end slit up half a centimetre is drawn well into the bladder and stitched on all sides to the muscular vesical walls. The guide is removed and the abdomen is closed, a gauze drain being left in in the event of leakage.

MEDICAL MUNIFICENCE.

IT is occasionally said that although members of the medical profession willingly render gratuitous service to hospitals they but rarely subscribe to the funds of these institutions; indeed, in the unhappy dispute that has recently arisen between the medical staff and the managers of the National Hospital for the Paralysed and Epileptic this taunt has been levelled against the staff. That the reproach is unmerited is well known to those connected with the management of medical institutions, and a conspicuous instance to the contrary is to be found in the donation of £5000 by Dr. A. Garrod Thomas as the nucleus of a fund for the erection of a new hospital at Newport. The Newport and Monmouthshire Hospital was established in the year 1867 with accommodation for 50 patients and for a time sufficed for the needs of the district, but the rapid growth of the town and the port placed a great strain upon the resources of the institution, and the outcome of Dr. Garrod Thomas's liberality has been the erection of a new building at a cost of about £30,000, of which all but £8000 have been subscribed. For the liquidation of the latter sum there was held in Newport for four days commencing Oct. 23rd a bazaar the proceeds of which contributed no less a sum than £5600.

PNEUMOCOCCIC PERITONITIS.

PNEUMOCOCCIC peritonitis, like pneumococcic arthritis,[1] is a condition which, though well known to continental writers, seems to have been less commonly recognised in this country. In children primary pneumococcic peritonitis is described as rather frequent by French writers. Cases have been described by MM. Sevestre, Dieulafoy, Brun, Moizard, Kirmisson, Galliard, Remy, and others. In adults, on the contrary, the disease is extremely rare. In the first volume of his valuable "Cliniques de l'Hôtel-Dieu" M. Dieulafoy states that only two cases out of 17 occurred in adults. At the meeting of the Société Médicale des Hôpitaux of Paris on July 13th M. Menetrier and M. Legroux described two cases. A vigorous, healthy man, aged 32 years, was suddenly seized with violent colicky pains unaccompanied by diarrhœa or vomiting. As they persisted he took on the third day a saline aperient which produced vomiting and passing diarrhœa. Continuing to suffer, he entered hospital on the sixth day with the typical *facies abdominalis*, drawn features and sunken eyes. The tongue was moist and furred. There were slight tympanites and diffuse abdominal tenderness. The urine was scanty and very albuminous. There was no fever. On the following days the pains were excessive and the tympanites became more marked and interfered with respiration. He vomited once and the stools were liquid. The temperature was subnormal, 96·8° F. Death occurred on the tenth day. At the necropsy general purulent peritonitis was found. The intestines were adherent to one another and to the abdominal wall. A coating of yellowish adherent pus covered the intestines, viscera, and abdominal wall. The pus when stained showed on slides numerous microbes of varied form. Cultures gave *colonies of the pneumococcus and colon* bacillus. The microbes other than the pneumococcus were thought to be of cadaveric origin. This case conformed to the type of ordinary acute septic peritonitis In the second case, on the contrary, the peritoneal symptoms were masked by others. A man, aged 35 years, was suddenly seized with acute abdominal pain, vomiting, and diarrhœa which ceased on the following day and were followed by constipation. There were tympanites and slight splenic enlargement. The pain diminished and was provoked only by pressure. The pulse was 115 and the temperature was 104·2° F. The urine contained one gramme per litre of albumin. Thrombosis of the right popliteal and left radial artery took place. On the twenty-second day the abdomen again became tympanitic and diarrhœa alternated with constipation. On the twenty-fifth day there was vomiting and a zone of dulness was found in the flanks. Persistent hiccough began and the patient became comatose. Two days later he died. At the necropsy two or three litres of reddish turbid fluid containing flocculi were found in the peritoneum. *Cultures yielded* the bacterium coli, the staphylococcus albus, and the pneumococcus. The pneumococcus was also found in a clot from the Sylvian artery which had been thrombosed recently—not more than 40 hours before death. The clot was composed principally of polynuclear leucocytes. There were infarcts in the spleen and kidneys. M. Menetrier and M. Legroux thought that the multiple thrombosis was *due to pneumococcic infection of the blood and that this* led to agglomerations of phagocytic leucocytes in the vessels which obstructed the circulation.

---

PROGRESS IN THE TREATMENT OF IDIOTS, IMBECILES, AND DEFECTIVES.

IN the Presidential Address before the Medico-Psychological Association, which is published in the October number of the *Journal of Mental Science*, Dr. Fletcher Beach referred to the progress which had been made in the treatment of "certain defective classes of society, such as idiots, imbeciles, the feeble-minded, the epileptic, and juvenile delinquents." The pioneer to whom belongs the honour of having created the true method of teaching idiots and imbeciles was Séguin, who in 1841 published his "Théorie et Pratique de l'Education des Idiots," based on his experience and the *means adopted by him for* training and educating idiots at the Hospital for Incurables in Paris. His work was continued at the Bicêtre, and five years later Séguin published his admirable book, "Traitement Moral, Hygiène et Éducation des Idiots, at des autres Enfants Arrières," which still continues to be the manual for all those who are interested in the education of idiots. Special institutions for idiots made their appearance *after* this in various countries—e.g., Guggenbuhl's Institution for Idiots at Abendberg, Switzerland (1845), Park House, Highgate (1848), and the Earlswood Asylum for Idiots, Redhill (1855). Since then various institutions have been provided for the same purposes, the most notable of these being the Royal Albert Asylum, Lancashire, for Idiots and Imbeciles of the Northern Counties (1870), and the Metropolitan Asylum at Darenth (1879) for the London district. Similar institutions have sprung up in Scotland, Ireland, the United States, and in Canada. With regard to the degenerates of the "moral imbecile" type, Dr. Fletcher Beach points out that whereas they were kept in prison 60 years ago they now find their way into institutions for idiots and imbeciles. They are a difficult class to deal with, for they are often intellectually sharp and clever, but they are thievish, lying, and *sometimes the subject of graver* criminal tendencies. The late Dr. Kerlin, who was superintendent of the Pennsylvania Institute for Feeble-minded Children, was *of* opinion that they should not be educated, as it increased their power for evil, but that they should live in separate buildings apart from other children in order not to infect them with their bad tendencies. Dr. Jules Morel of Belgium has stated that they should be received into special "institutions for the degenerate," as they are not fit subjects for lunatic asylums, reformatories, or prisons, in which opinion Dr. Fletcher Beach concurs. In 1899 the Elementary Education (*Defective and Epileptic Children*) Act was passed, whereby a school authority may make arrangements for ascertaining "what children in their district, not being imbeciles, and not merely dull or backward, are defective—that is to say, what children by reason of mental or physical defect are incapable of receiving proper benefit from the instruction in the ordinary public elementary schools," so that they can be sent to special classes in institutions provided by the local authority for their education and training. Indeed, such special "classes" had already been established and in operation since 1892 in parts *of London, Leicester, Birmingham, Brighton, Bristol,* Nottingham, and a few other towns, so that when the Act came into force in 1899 its provisions of the Act at once became efficient. Dr. Fletcher Beach refers to similar establishments on the continent and in the United States and he hopes that much good will come from them. Reference is made to "colonies" and farms for epileptics which are regarded as useful medical institutions which may *be made in a measure self-supporting. The growing tendency* of recent legislation to provide reformatory treatment or detention in an industrial school for youthful offenders is also praised *as a step in the right direction.*

DENTAL SURGERY AND THE SERVICES.

A MATTER of considerable importance in connexion with War Office reform is dealt with in the current number of the *Journal of the British Dental Association* in an article entitled, "On the Need for the Recognition of the Assistance of Dental Surgeons by the War Office and Admiralty." The writer of the article, after reviewing the attempts which have been made in the past to initiate the institution of some system by which efficient dental assistance might be provided for our soldiers, sailors, and recruits, proceeds to discuss the conditions which obtain at the present time in *this country* and in various *foreign* States. He criticises severely the list of instruments provided for the use of army surgeons, and brings evidence to show that there is "no effective conservative *dental aid* provided in the British Army." He then deals at length with the regulations issued by the War Office and Admiralty for the guidance of medical examiners of candidates for commissions and of recruits, a large number of whom are rejected, when otherwise fit, solely on account of defective teeth, whereby a great loss to the nation is needlessly incurred. Great stress is laid in the article on the point that in making these examinations army surgeons are placed on a footing entirely different from that of their civil brethren, inasmuch as they are called upon to pass judgment on work executed by qualified dental surgeons of a kind which they themselves would be the last to undertake to perform. The Bill now before Congress in the United States of America, which has *passed the Senate Committee, to provide* contract dental surgeons without military rank for the American army, is referred to and the article concludes by suggesting the lines upon which reform might be effected in this country. After pointing out that there are many difficulties in the way of any change analogous to that provided for by the American Bill the writer of the article shows that the treatment of recruits is perfectly feasible, and he insists further that the assistance of dental surgeons in the examination of candidates for commissions and of recruits is called for in justice to all concerned—namely, dental surgeons, army surgeons, the candidates themselves, and the nation at large.

CITY AND COUNTY OF CORK MEDICAL AND SURGICAL SOCIETY.

THE meetings of this society were resumed on Oct. 24th and the president, Dr. Henry Corby, professor of midwifery in Queen's College, Cork, took "The Medical Profession" as the subject of his inaugural address. Membership of such a society as theirs, he said, had the great advantage for medical men in general that it provided them with opportunities for speaking in public and aided them in acquiring that most useful accomplishment, the ability at any moment to express their ideas in a few pithy sentences. Oratory in the true sense was a rare talent, but even the least pretentious of public utterances lost something of its effectiveness when the speaker was unpractised—a fact not always remembered as it ought to be, for men of great mental endowments had been known to become embarrassed when suddenly called upon to make a speech after dinner. After referring to the multiplicity of authorities granting degrees and licences and the difficulty experienced by the general public in appreciating the differences which exist between the various qualifications Dr. Corby asked, "Why not establish the one-portal system?" and proceeded to point out the advantages of the uniformity which would thereby be secured He then touched on the falling off in medical fees caused by competition and overcrowding in the profession, but pointed out that there was another side to the picture. "If we love our profession," he said, "our hard work becomes a pleasure. The pain and suffering we daily witness lose much of their sting as we have the glorious consciousness of having relieved them. Can we not count on the respect and esteem of our neighbours and the unsolicited blessings of the poor?"

INFLAMMATION OF THE SPHENOIDAL SINUS.

IN the October number of the *Archives Générales de Médecine* Dr. Toubert of the military hospital of Val-de-Grâce, Paris, publishes a very long paper on the intracranial complications following disease of the sphenoidal sinus, giving full details of two cases which have come under his personal observation, together with a summary of 22 others collected from various sources. The most usual age for this disease is from 20 to 45 years, and the exciting cause is infection, sometimes by the bacillus of influenza, but principally by the pneumococcus or diplococcus of pneumonia, and by the staphylococcus and the streptococcus, which occur both in the pus of the sinus and in that of the meninges, the organisms having made their way to the sphenoidal sinus from the nose, the pharynx, or another sinus. Infection may take place directly in connexion with a general disease such as pneumonia or erysipelas, or indirectly (1) after febrile diseases, such as typhoid fever, and especially influenza which holds the first place in the list of exciting causes, or (2) after chronic diseases, such as syphilis, which tend to produce necrosis of bone. Dr. Toubert's first patient suffered from influenza, and it was through this disease that an entrance was provided for the streptococcus which set up the inflammation of the sphenoidal sinus and the subsequent meningitis. No adequate information has been collected with respect to the absolute frequency of disease of the osseous sinuses in general; many of these conditions are unrecognised during life and only discovered at necropsies. The sphenoidal sinus is, however, less liable to disease than the maxillary sinus. Diseases of the ear as a cause of intracranial complications have been carefully studied, but less has been done with regard to the perinasal cavities; there is, however, evidence that suppuration of the sphenoid bone and of its sinus is an important cause of meningitis. Pus may be formed both on the surface of the mucous lining of the sinus and also between the mucous lining and the bone, so that the mucous membrane is converted into a bag of pus floating in pus and secondary osteo-periostitis of the osseous walls is relatively frequent. Sometimes only the bone is affected (primary caries of the sphenoid), the mucous membrane being almost exempt; this often occurs in syphilis. The thinness of the bones, the special virulence of the infective agent, and the preceding necrosis of the mucous membrane are probably the chief conditions which favour osteitis. Perforation of the osseous walls of the sinus has been found in about two-fifths of the cases, not including antero-inferior perforations which do not lead to cerebral complications. The possible secondary lesions affecting the dura mater and the venous sinuses are abscess, either intradural or extradural, and phlebitis of the coronary or cavernous sinus. Abscesses are rare. Phlebitis may be considered to be the special intracranial lesion following inflammation of the sphenoidal sinus, just as intracranial abscess follows inflammation of the frontal sinus and meningitis follows ethmoiditis. Cerebral abscess proper seems never to have been found after suppuration of the frontal sinus. Weichselbaum has recorded the case of a robust young soldier who was carried off in two days by a febrile disease, accompanied by vertigo and vague pains in the face, forehead, and neck; the result of the necropsy was almost negative, but there was infection of all the sinuses of the face and the skull. Dr. Toubert therefore considers that these sinuses and the nasal fossæ should be examined in unexplained deaths following a short illness. In cases of meningitis it is usual to examine the osseous sinuses when their walls have been seen to be perforated, but the sphenoidal sinus is not always thought of, even though ocular or orbital symptoms during life may have drawn attention to the cavernous sinus of the dura mater or to the sensory or motor nerves of the eye. In Dr. Toubert's two cases the lesion of the sphenoidal sinus was discovered only at the necropsy, for there were no clinical symptoms pointing in that direction. In the first case that sinus was opened in the course of a search for the cause of a meningitis unattended by osteitis of the temporal bone. In conclusion, he gives a detailed account of Jacob's method of catheterising the sphenoidal sinus, a method which he prefers to that of Zuckerkandl.

INEBRIETY IN WOMEN.

A SPECIAL meeting of the council of the Charity Organisation Society was held on Oct. 29th at the Royal United Service Institution. The chairman was Dr. W. J. Collins who is chairman of the Inebriates Acts Committee of the London County Council. Mr. C. S. Loch suggested the following as subjects for discussion: 1. Is inebriety increasing amongst women? 2. What methods are to-day being adopted under the Habitual Drunkards Act and the Inebriates Acts? 3 Can any suggestions be made for dealing with cases of women in connexion with recent institutions, if possible, during the earlier stages of the disease? 4. Can such cases be dealt with apart from, or in connexion with, institutional treatment? The chairman pointed out that there should be greater coördination between the committing authority and the receiving authority. The task before them was to rehabilitate such women. It was said that inebriety was increasing amongst women but it was very difficult to arrive at the truth. In the discussions which followed the opinion was expressed that grocers' licences should be done away with and that sooner or later a State reformatory would have to be established for bad cases. The question of grocers' licences and of other legislation was eventually referred to a committee of the council. Whatever be the cause, whether mental instability or the greater secrecy with which the vice is practised, we believe that it is a fact that a woman drunkard is harder to reform than is a man. The Inebriates Acts are at present almost a dead letter owing to the lack of accommodation provided for cases committed by magistrates and until such accommodation is provided either by the State or by municipal or private help it is difficult to know how these unfortunate creatures can be benefited. We are glad, however, to see that two such bodies as the London County Council and the Charity Organisation Society have the matter under consideration.

BIRMINGHAM CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION.

THE report of the committee of the Consultative Medical and Surgical Institution, Birmingham, has been issued. "The income and expenditure account shows a deficiency of £343 13*s.* 6*d.* on the working of the institution to date, but the committee believe that before long this debit balance will disappear and the institution will become self-supporting." We quote from the *Birmingham Post*, where the committee are also credited with the view that they "consider it very satisfactory that these results should have been obtained in so short a time, notwithstanding the organised hostility of certain members of the medical profession." The committee would seem to be easily pleased, while if any member of the medical profession is interested to learn why the profession ought not to think well of the institution he is referred to THE LANCET of May 20th, 1899 (p 1374), and June 2nd, 1900 (pp 1595 and 1633).

ROYAL COLLEGE OF SURGEONS OF ENGLAND: ANNUAL MEETING OF FELLOWS AND MEMBERS.

ON Thursday, Nov. 15th, will be held the annual meeting of the Fellows and Members of the Royal College of Surgeons of England at 3 P.M., when the Council will present their annual report. At this meeting any Fellow or Member may bring forward any motions which may be accepted by the Council, but it is necessary that any proposed motions should be sent into the Secretary at once or it may be too late. The subjects mentioned in the report are numerous and interesting, but the items of most importance are undoubtedly the centenary of the College and the creation of the Honorary Fellowship. A full account of the proceedings is contained in the report, a copy of which is sent to every Fellow and also to every Member who applies for it. We hope that the meeting will be largely attended both by Fellows and Members and that some subjects of interest and importance to all the alumni of the College will be brought forward for discussion.

THE THANKSGIVING SERVICE AT ST. PAUL'S CATHEDRAL ON THE RETURN OF THE CITY IMPERIAL VOLUNTEERS.

THE thanksgiving service at St. Paul's Cathedral was a very impressive ceremony. Although it did not commence until nearly two hours after the appointed time the congregation was not entirely ignorant of the scenes which were passing in the streets. First, the news was whispered round that the procession had been broken by the crowd; then later it was feared that the Volunteers would probably not succeed in getting through at all and that very probably the service would not take place. From time to time the great west door was partially opened and a view was obtained of the upper windows of the houses and of the flags which hung across Ludgate-hill. At length flags and handkerchiefs were waved, the sounds of cheering, first distant, then nearer and louder, were heard, and at last the City Imperial Volunteers appeared. But even in the cathedral their procession was not continuous, and some stragglers appeared after the commencement of the service. The men looked very tired. There were many earnest, thoughtful faces and many eyes dimmed with tears. The address of welcome given by the Bishop of Stepney was straightforward, hearty, manly, and brief. The congregation joined heartily in the hymns and in singing the National Anthem. The *Te Deum* was sung to music by Professor Villiers Stanford. Those who were privileged to take part in the service are not likely to forget it, and only those who have attended on such an occasion at St. Paul's Cathedral can quite appreciate the beauty of an English service at its best.

THE Working Men's College, 46, Great Ormond-street, has for some months had an ambulance class in connexion with the college, but the class is at present without an instructor, as the gentleman who has hitherto been acting in that capacity has been compelled to relinquish the duties owing to ill-health. We have been requested to publish an appeal for a volunteer and we do so with pleasure. All the work is done in the evening and every effort will be made to fix a time to suit the convenience of the instructor. Communications should be addressed to the secretary, Mr. E. C. Duchesne, at the college.

ANNUAL congresses of Russian physicians and surgeons have been established at Moscow. The first meeting will be held on Dec. 28th, 29th, and 30th, 1900. The following officers have been elected for the organisation of the Congress:—President: Professor Diakonow. Vice-President: Professor Bobrow. Secretaries: Dr. Rein and Dr. Derewjinsky. Treasurer: Dr. Bereskin. Members of the Committee: Professor Sinitzin, Dr. Soloview, and Dr. Martinow.

THE Sanitary Inspectors' Association of South Wales and Monmouthshire met at Port Talbot on Oct 27th. Mr. Edward Knox, J P., C.C., the chairman of the Margam District Council, in an address to the members expressed the opinion that all medical officers of health should be debarred from private practice and that small districts should be combined under the supervision of one officer.

WE deeply regret to announce the sudden death on Saturday last of Mr. William Anderson, surgeon to St. Thomas's Hospital and professor of anatomy to the Royal Academy. An extended obituary notice will appear in our next issue.

DR. THOMAS BUZZARD has been selected as a representative of King's College on the Senate of the University of London, vice Lord Lister, resigned.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The concession granted by the Council for the Primary Fellowship for Licentiates of the College in recognition of the Royal visit to Ireland has been extended to July 31st, 1901, in the case of Licentiates of the College engaged in the present war or resident abroad.

DIPHTHERIA AT BAMPTON.—A largely attended meeting was held at the Public Rooms, Bampton, Devonshire, on Oct. 20th to impress upon the sanitary authority the necessity for taking immediate steps to stamp out the epidemic of diphtheria which has for some months past been in existence in the town. A large employer of labour stated that if the council would not move in the matter he would build houses for his men and their families in a spot where they would be sure of good sanitary arrangements.

materia medica, have been housed on the second floor in the north corridor, and there are well-arranged collections of specimens in all these departments.

In every direction evidence is shown of an earnest endeavour to provide for each individual student the means for practical work while the lighting and the general arrangements of details call for praise.

THE WAR IN SOUTH AFRICA.

THE events in South Africa, although they have been of a stirring kind, are nevertheless easily chronicled. The annexation of the Transvaal was proclaimed at Pretoria on Oct. 25th and with it came to an end, as far as its officials are concerned, a most oppressive form of Government which, if we may believe only half the evidence and facts which are alleged to have been brought to light, was animated by a selfish spirit of monopoly and aggrandisement, and maintained by a system of fraud and corruption. As regards the Boer forces, if they have been dispersed over the country they are nevertheless extremely active in prosecuting a harassing system of marauding and in making raids in various directions. The Rob Roy of the situation is the very able and ubiquitous leader De Wet, aided by Botha, and until one or both of these are captured the British troops will continue to be subjected to attacks and find plenty of occupation in repelling them.

The City Imperial Volunteers have returned to this country and have been accorded the welcome which they merited for their pluck, soldier-like qualities, and services in the field. Out of a total strength of 1729 of all ranks, nine were killed, 43 have died, 53 were wounded, and 141 were invalided—a total of 246 or slightly over 13 per cent. This was up to the date of their embarking from the Cape, but several deaths on the voyage home have unfortunately to be added to the number. Lord Roberts's address to the City Imperial Volunteers strikes us as not only one which any corps might be proud to have received, but as very happy in its allusions; "and," says his lordship, "there is one other thing you can do—that is, to carry into the heart of the nation what you now know of the British soldier, with whom you have fought shoulder to shoulder for some months past. Tell every one of his bravery, his endurance, his gentleness, and his good behaviour. Tell them what a noble fellow he is, and how, at a moment's notice, he is prepared to lay down his life for his Queen and country." It is well to be reminded of this "lest we forget." Our readers will recall the incident of the American soldier's remark to the gushing and effusive young lady: "Beg pardon, miss, I am not a hero. I am only a regular."

War and death spare none, and it was a sad coincidence that the news of the untimely death of Prince Christian Victor, a grandson of the Queen, should have reached this country at the time of the return of the City Imperial Volunteers, and have imparted a note of pathos to Her Majesty's gracious message to them.

As regards the question of the arrangements for the sick and wounded the management of the war hospitals and the efficiency of the medical service in the field we shall all feel glad when the Royal Commissioners have concluded their investigation and furnished their report. Meanwhile we may call attention to two articles which have appeared—one in the October number of the *Edinburgh Review* headed "The Sick and Wounded in South Africa"; the other in the first number of the *Monthly Review*, a new and important publication issued by the firm of John Murray, Albemarle-street, entitled "Surgical Experiences in South Africa," by Mr. A. A. Bowlby, F.R.C.S. Eng. Both of these articles are well worth reading at the present time. There has been a very lively passage of arms between Mr. Winston Churchill, M.P., and the Earl of Rosslyn in regard to certain allegations contained in a volume recently published by the latter. Mr. Winston Churchill gave a lecture on the war in South Africa on the evening of Oct. 30th, when Lord Wolseley occupied the chair and made a speech.

SIX MONTHS' EXPERIENCE IN THE SOUTH AFRICAN CAMPAIGN.

CAPE TOWN, APRIL; BLOEMFONTEIN, MAY; SPRINGFONTEIN, JUNE AND JULY; PRETORIA, AUGUST AND SEPTEMBER, 1900.

By J. LYNN THOMAS, F.R.C.S. ENG.,

SENIOR SURGEON, WELSH MILITARY HOSPITAL; HONORARY SURGEON TO THE HAMADRYAD HOSPITAL, CARDIFF, ETC.

When I left England on March 3rd I entertained certain definite ideas regarding the duties of a surgeon in connexion with the treatment of penetrating and perforating wounds of the abdomen. I also imagined that the experience of this war would in all probability settle the respective and relative claims of bobbins, Murphy's buttons, Laplace's forceps, *et hoc genus omne*, in the field of intestinal surgery. To-day (Oct. 6th) I return to England having long abandoned the ideas which I possessed on my outward journey, and the question of the expediency of using mechanical aids for facilitating intestinal suturing is just where it was before the outbreak of hostilities.

Perhaps one of the greatest surprises in the surgery of this war has been the extraordinary success which has followed the *noli me tangere* principle of treatment of abdominal and thoracic perforating or penetrating wounds. It was perfectly astounding to find that the exit wounds of bullets which had traversed the intestinal cavity healed up as kindly as did those of entrance—in fact, the wounds healed up as quickly as if they had been inflicted by a modern surgeon in his operating-room after elaborate preparation of the skin. How a bullet can go through fæcal matter and then bore a hole which heals up without any septic complications is indeed a mystery to me. An officer who was under my care in Pretoria was shot near the spine in the right loin. The bullet came out in his perineum and then went through his foot, having traversed the rectum and urethra. The wounds in the body healed without trouble, as did that in the foot, the only serious annoyance being a few drops of healthy urine coming out from the perineum wound I saw the wounds in the rectum, so that any hypothetical explanation is unnecessary. In one case where a bullet entered over the cæcum and came out behind the left trochanter major and gave rise to melæna and hæmaturia it was seriously suggested that they were due to bruising alone. Why some men think that a Mauser bullet does not perforate intestine in such cases of easy recovery I do not know. The conditions calling for cœliotomy in bullet-wounds (Lee-Metford and Mauser) must be very rare and the recognition of those conditions must be a matter of extreme difficulty.

LODGED BULLETS.

As a rule there should be no hurry in removing bullets which have traversed either the abdomen or the thorax, no matter how temptingly near the skin they may be. They should be left alone for two or three weeks—that is, until the bullet track is firmly healed and the extravasated blood is absorbed: two splendid media in which to grow pathogenic germs. After this period no serious harm is done should the operation wound become septic. I saw a case of hæmothorax converted into one of empyema by the removal of a bullet which was under the skin of the back. The *lacerated* entrance hole in front healed up by first intention, whilst the *incised* wound of the operation suppurated and nearly cost the patient his life.

Operation for hæmothorax is very rarely required. We had one case in which the heart was pushed to the right of the sternum and by careful nursing the patient got well rapidly. A bullet entered the mass of the pectoralis major and got lodged in the skin of the posterior fold of the axilla, giving rise to an enormous hæmatoma in the axilla. At the end of three weeks the bullet was easily removed, and should suppuration have set in there would have been no fear of extension beyond the wound. "Tommy's" desire to have his bullet "cut out" is almost morbid. I think there is a superstition in the army that bullets wander about in the body until some vital spot is reached and that on that account they should be "extracted." We generally had trouble with officers as well as with "Tommy" when advising them not to have an operation done in cases where the bullets were deeply imbedded and giving rise to no symptoms whatever, but most of them soon realised that metal in the body is not harmful if surgeons put common screws in broken bones in civil life without any hurt.

THE TELEPHONE-PROBE.

My wife having read an article by Mr. Frederick Treves on the telephone probe sent one for our use. As I have not seen a medical journal since I left home I do not know what my former teacher and friend may have written about this instrument, but a few remarks may not be superfluous, as not one of the many surgeons whom I saw from Cape Town to Pretoria had had any experience of it.

The telephone-probe is one of the most useful and reliable *instruments for locating metal during an operation.* The position of Roentgen photography in the process of localisation of bullets and foreign bodies had been fairly well defined before this war, and any surgeon who has had much experience in operating knows from painful disappointment how easy it is just to miss the foreign body by one-sixteenth of an inch in situations where any small transverse cuts may involve the division of a nerve or a tendon. During an operation for a deeply imbedded bullet, retraction of the lips of the wound or the placing of the patient in a suitable position for operation—this being slightly different from that in which the Roentgen photograph was taken—often creates a disturbance of the straight line of known depth from the skin to the bullet. It is this disturbance of relationship which sometimes leads to failure in finding the bullet and is one of the causes of unnecessary and reckless exploration to extract the bullet at any cost. It is just in these conditions of difficulty that the telephone-probe comes to the rescue. The usefulness of Roentgen photographs terminates before starting an operation, whilst that of the telephone-probe comes in *during* the operation. Nélaton's probe, Fluhrer's probe, and other probes will surely become historical relics *as soon as the telephone-probe gets generally known.* The narration in brief of two cases will be sufficient to illustrate the particular points in which the telephone-probe becomes invaluable.

CASE 1.—Private ——, aged [illegible] years, was shot in the back

gave rise to pain during deep breathing, with rigidity and tenderness of the mass of muscle between two of the tendinous intersections of the left rectus abdominis. On July 12th, under 1 per cent. of cocaine, I opened the anterior abdominal wall until something was felt which I mistook for the bullet. The patient could not stand the pain of further exploration, so he was anæsthetised and the wound was enlarged upwards. Again I thought I had the bullet, but ordinary traction on the forceps did not displace it. I then tried the blunt-pointed probe, and Professor A. W. Hughes was listening when I touched the quasi-bullet. There was no "ring" at the telephone, but on exploring more deeply through the inner edge of the wound the bullet rang the telephone, and it was easily removed. I had applied the bullet forceps first to the cartilage of the eighth rib and then more deeply to one of the ribs, and in this case the differentiation of cartilage, bone, and bullet was quickly made out. When I started operating I felt that the removal of the bullet was an easy matter. I should have abandoned further search for the bullet if my friend Professor Hughes had not reminded me of the gift which my wife had made to the hospital. This was the first occasion on which it was unpacked. After this incident the further exploration for bullets was simplicity itself and my colleague, Mr Mills-Roberts, has also had some very interesting and instructive cases in which the probe was used.

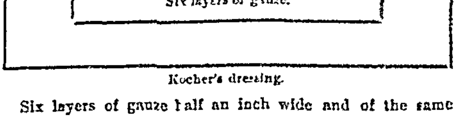
CASE 2—On August 23rd, 1900, Trooper —— was shot near Belfast by a ricochet bullet through the back immediately below the spine of the left scapula. After the wound had healed skiagrams were taken and the bullet was located on the outer anterior aspect of the surgical neck of the humerus. It gave rise to much pain round the joint and upon movement of the shoulder. On Sept. 15th, under ether, I pushed the sharp-pointed probe through the skin and very soon, before incising the skin, I found the bullet. After making an incision to the surface of the deltoid I separated the fibres of the muscle until I exposed what felt like the bullet slipping under my finger *before proceeding to incise* the encapsulated (?) bullet. The probe was used, and to my surprise there was no "ring" On exploring the outer edge of the wound the telephone rang and the bullet was extracted. The feel of the bullet, encapsulated with a little fluid around it, was most difficult to differentiate by touch from that which I mistook in the first place to be the bullet but which turned out to be the tendon of the biceps. The probe in this case saved the opening up of the sheath of the tendon of the biceps—a procedure which might in time have entailed pain about the joint owing to adhesions forming upon avoidable traumatism.

FORCEPS-TOURNIQUET.

Last February I exhibited at a clinical meeting of the Medical Society of London a long-bladed forceps which had been used instead of an ordinary tourniquet in every amputation which I had performed for the last two years, and it appeared to me that it would be of service in military surgery. The conditions in South Africa requiring the use of a tourniquet have been so few, owing to the splendid success of conservative surgery in saving limbs, that I have had but few opportunities of testing it; but as the surgery of war is practically identical with the surgery of civil life, I think that the forceps-tourniquet would be found more handy and reliable than the elastic band or Esmarch's tourniquet. India-rubber deteriorates very quickly in climates like that of India and the one we have experienced in this campaign. To sterilise an Esmarch's tourniquet is not at all a simple and quick procedure under conditions which demand economy of antiseptics and time; it is necessary to have one assistant to apply an Esmarch's tourniquet in amputation at the hip or the upper third of the thigh; whilst every surgeon should in an emergency feel that he could perform single-handed any amputation with speed and confidence. The forceps-tourniquet has none of the disadvantages of the rubber band. It can be applied to control hæmorrhage during disarticulation at the hip or any amputation of the lower limb in 15 seconds, it is under the sole control of the operator, it can be slackened and re-clamped in a second, and, as far as my own observation goes, it does not give rise to the worrying vasomotor paresis which follows upon the removal of the rubber band. At Springfontein I had the opportunity of demonstrating its use to Lieutenant-Colonel A. H. Keogh, R.A.M.C., and his staff in a case requiring amputation through the upper third of the thigh, and Lieutenant Colonel Keogh and Mr. J. E. Ker (the latter of whom performed the operation) were pleased and surprised at the small amount of blood which was lost. For field hospitals and bearer companies I think the forceps-tourniquet would be found very handy on account of its portability and asepticity. A shield filled with an antiseptic jelly can be fitted over the smooth blade which is placed under the blood-vessels, and the instrument can be clamped on to the inside of the breast of the surgeon's tunic when on the trek. I hope soon to publish some cases with illustrations on the methods of applying the tourniquet in cases of amputations of the upper and lower limbs.

ONE MOP AND TWO PAIRS OF GLOVES FOR OPERATIONS.

It is important to economise mops, or sponges, and dressings as much as possible in order to reduce the quantity of packages for transport and at the same time to maintain efficiency. All our aseptic operations were performed without the use of any antiseptic lotion and a very small steriliser was all that we required for any operation. The thread gloves were taken out of the steriliser and worn by the operator and his assistant, and the one mop did not usually leave the hands of the assistant until the operation was completed. For example, we had a radical cure of hernia and excision of long portions of both internal saphenous veins and also removal of big bunches of varices from both legs performed at one sitting on a colonial soldier with only one mop, and the same also in amputation of the thigh, &c. The most economical and efficient dressing for operation wounds that I know of is what I should call a "Kocher's dressing," having seen it at Professor Kocher's clinic about three years ago. It is generally the only dressing which is applied in cases of nephropexy, ovariotomy, radical cure of hernia, trephining, &c. It answers admirably in civil practice and it was equally satisfactory at our stationary hospital. The diagram illustrates the points of this simple dressing:—



Kocher's dressing.

Six layers of gauze half an inch wide and of the same length as the wound are placed over the line of sutures and are kept in place by a single layer of gauze extending about two inches in all directions and fixed by collodion. The advantages of Kocher's dressing are its simplicity, its cheapness, its compactness, and its non-interference with the sutures when taking it off for removing them.

THE ARMY REGULATION CASE.

I would venture to suggest the reconstruction of the present army regulation case because it is lacking in portability and contains instruments which belong to the pre-anæsthetic era and which have long been discarded in civil practice. There are patterns of operating bags in civil practice which might with advantage be copied. Instruments carried in slots, &c., in solid metal trays are very well in a surgical instrument maker's shop, but when they get bent or twisted they become extremely unsatisfactory in use; trays made of one piece of hard wood are much more reliable. The ordinary probe gives more pain to the patient than is called for; it often infects wounds; and it is a question for serious consideration whether it should not be discarded from use except during the performance of an operation. It is a reminder of the surgical age when sinuses were treated by a single slap-dash incision and plugging of the gash made.

THE ROYAL ARMY MEDICAL CORPS AND THE CIVIL MEDICAL OFFICERS.

I confess that my impression of the organisation of the Royal Army Medical Corps is much more favourable after being taught its practice and routine work by the most able and capable administrator of the Welsh Hospital, Lieutenant-Colonel A.H. Keogh, R.A.M.C., than it was. When this officer took over the charge of our hospital he said: "You will know as much about our organisation and the so-called mysteries of our specialised work in a month as I do." I confess that he over-estimated the capacity of his pupil for acquiring knowledge, but the manner in which the opinion was given and the desire to teach and explain the why and the wherefore of the many details of the work made our task a very instructive, interesting, and agreeable one.

I think it would be highly desirable for the authorities to confer a temporary rank upon all civil medical officers who hold no commission when their services are required to assist the Royal Army Medical Corps. From force of habit "Tommy" has got into the way of looking at shoulder-straps and not at the faces of individuals who enter the hospital. It is much easier to keep order in camp, to have orders promptly executed, and to have general smartness amongst convalescent patients when a civilian surgeon has stars on his shoulder-straps. Another advantage of a temporary rank would have been to prevent a few members of the Royal Army Medical Corps from treating the civil medical officers as if they did not belong to the same profession. I heard several men complain of being treated in that manner by officers of the Royal Army Medical Corps and discussing philosophically some means by which such conduct could be obviated in future. There should be no excuse for the principal medical officer of a hospital driving his civilian medical officers to mess separately, as they undoubtedly were in some hospitals. This was very fortunately not the custom in the majority of hospitals, and consequently the work was done most satisfactorily by a united and contented staff. On the whole, perhaps, it is the individual, and not the system, that is so much at fault. If that be so, the right way to improve the individual is to make the Royal Army Medical Corps more tempting to the best men by better pay and by compulsory and regular leave for study in organised schools for such work. Promotion should mean ability and not seniority alone.

ENTERIC FEVER AND DYSENTERY.

I do not know what the type of dysentery was in Bloemfontein, but judging from the sad and painful fact that three of the staff of the Welsh Hospital died from it—one at Bloemfontein and two at Springfontein soon after leaving the former place—and also bearing in mind the circumstance that they had the best nursing possible and also the advice of men of known ability and experience, one cannot but admit the probability that the germs of the disease had acquired a degree of malignancy which fortunately is quite exceptional. This took place in May when almost everyone in Bloemfontein suffered from gastro-enteritis of variable intensity due to the air being polluted by dust carrying germs from dried excreta and dead animals, &c.

An officer who was treated for enteric fever at Springfontein pointed out the way in which the water-supply of the troops of which he was in charge got contaminated and I think this worth relating. They had been encamped for some weeks about three-quarters of a mile below a railway-bridge and the water-supply was got from the river and was considered good because no houses, villages, or troops were near its banks for many miles up the river. All the trains coming down the line stopped on the bridge to get water for the engines, and it was discovered that hospital trains conveying enteric fever patients coming down the line always took advantage of the stopping on the bridge for clearing out the stools of those cases which happened to be in the train and also to clean the bed utensils. Owing to the formalities which the "regulations" required it took some weeks before the river contamination got stopped.

BULLET-WOUNDS AND THEIR SEQUELÆ.

One of the peculiar results of Lee-Metford and Mauser bullet-wounds was the comparatively small skin scar and the relatively large size of the subcutaneous scar in the soft tissues. In one case a bullet entered through the cheek and came out through the lower part of the thorax posteriorly. The patient was well when I saw him, but he had paralysis of the inferior mental nerve and the hypoglossal and sympathetic nerves on the same side, and an enormous scar-cord could be felt from the angle of the jaw for about three inches. Whether the paralysis was due to direct lesion of the nerves by the passage of the bullet or whether the nerves got subsequently involved in the scar tissue, I do not know. The large subcutaneous scars are due to the devitalisation of the matrix holding the fluids of the body all round the track of the bullet. The velocity of the bullet causes hydro-dynamical displacement of fluid so acutely and suddenly that the shock impairs the vitality of the living matrix. An experiment on a fresh turnip shows well the devitalising, bruising, or pulping effect beyond the track of the bullet. By making a section at right angles to the track made by a bullet shot through a turnip and exposing the cut surface to the air, one can watch the changes of colour between the bruised and the unbruised parts. The extent of the pulping all around the track varies according to the succulence of the turnip. It is probable that many of the immediate results as well as the sequelæ of bullet-wounds are due either to this hydro-dynamical shock, or, later, to the nipping of important structures, such as nerves, in the scar of the devitalised tissues.

ANEURYSMS.

I should think that the safest course to adopt in treating aneurysms which develop two or three weeks after traumatism, is to lay open the blood-tumour, turn out the clots, and tie the ends of the vessels.

CASE 3.—I saw an interesting case in consultation at No. 2 General Hospital, Pretoria, where two large pulsating tumours followed a wound made by a bullet passing through the opening in the adductor magnus for the passage of the femoral vessels. One tumour was on the inner side of the inner hamstrings, whilst the upper half of the popliteal space was occupied by the other tumour. It was not easy to differentiate the two tumours. An incision was made over the inside of the thigh, the blood-clot was turned out, and then the stretched opening in the adductor was enlarged sufficiently to turn out all the clots from the popliteal aneurysm, and the gaping mouths of the popliteal artery and vein were tied in the popliteal space, whilst on the inner surface of the adductor tendon—i.e, the lower portion of Hunter's canal—the other ends of the femoral artery and vein were tied. In this case the blood-vessels were injured where the femorals become popliteals, with the consequent yielding of the scar in the vessels on either side of the adductor opening. The patient was getting on well a week after the operation.

CASE 4.—In consultation at No. 3 General Hospital, Springfontein, I saw another case of popliteal aneurysm following a perforating wound through the patella. The tumour extended for the whole length of the space and down into the calf. An incision was made over the ham, the blood-clots were turned out, and the artery and the vein were found to be divided and the two had to be ligatured at both ends. The patient made a good recovery.

Now in both Cases 3 and 4 the symptoms pointed only to what is called an aneurysm, and in both of the cases the veins were also found to be opened and communicating with the blood extravasated, although they did not show any physical signs of the condition. It is much safer to treat these cases as if they were subcutaneous traumatic rupture of the blood-vessels. This, in fact, they are, the only difference being that the injured walls of the vessels give way some days or weeks after the original injury. I know of cases in which the artery was tied above by Hunter's operation—a much easier operation—but they were followed by gangrene. As long as the large blood-tumour is left it is a serious obstacle to the collateral circulation after proximal ligature of the main artery.

INJURY TO THE INTERNAL SAPHENOUS AND GREAT SCIATIC NERVES, WITH ANEURYSMAL VARIX IN HUNTER'S CANAL.

CASE 5.—A newspaper correspondent was shot through the thigh on August 21st, 1900, near Belfast. When admitted to the hospital the entrance wound and the exit wound in the front and at the back of the middle of the thigh were healing kindly with no evidence of subcutaneous extravasation of blood. There was absolute anæsthesia over the distribution of the internal saphenous nerve with anæsthesia dolorosa over the middle two thirds of the inner aspect of the leg. There was also anæsthesia, but not complete anæsthesia, over the distribution of the anterior tibial and musculo-cutaneous nerves, but there was no motor paralysis. The diagnosis arrived at was that the internal saphenous nerve had been divided in Hunter's canal, and that the outer edge of the great sciatic nerve—or, if it had already divided, the external popliteal nerve—was in a state of paresis due to the hydro-dynamical shock which I have already referred to. We were all surprised that the blood-vessels had escaped, considering the nerve lesions and the position of the wound. On Sept. 4th—i.e., a fortnight after the accident—an aneurysmal varix formed in Hunter's canal, and on the 8th I tied the femoral artery immediately above the original injury by separating the fibres of the sartorius muscle instead of displacing it, which requires a longer incision. Recovery was uneventful. The fact that a bullet can pass anteroposteriorly between the superficial femoral artery and the vein and divide its accompanying nerve without giving rise to immediate dangerous hæmorrhage is almost on a par with the surprising fact that perforations of the intestine will close without the aid of a surgeon.

EXPLOSIVE OR EXPANDING BULLETS.

I saw but few cases of wounds which had been caused by explosive or expanding bullets. In all of the cases the bone had been shattered, and the few cases which suppurated, as well as the veldt sores, were treated by the application of pure tincture of iodine.

I [illegible] arriving in Pretoria of examining [illegible] Consul-General, Colonel Stowe, [illegible] Mauser bullets south of Kroonstad, and as our train was the next to go to Pretoria with passengers after the line was repaired we naturally took a lively interest in the character of the bullet-holes in the carriage. There was one bullet-hole above the ventilator of one of the windows which before a full examination I took to be due to the effect of an explosive bullet. Between the inner and outer wall of the ventilator there was a space of about two inches The outside had one clean-punched hole which was the hole of entrance, whilst on the inside wall there were six jagged perforations covering an area of six inches by three inches. The bullet in traversing the interspace between the inner wall and the outer wall struck a thin piece of cast iron and was broken into six fragments, and it left behind in the space a piece of the outer covering. Everyone who saw the condition felt that it was undoubtedly an example of the effect of an explosive bullet. Through the courtesy and kindness of Colonel Stowe and Major Gordon, Railway Staff Officer, I was allowed thoroughly to examine the carriage and to make plain the use of what most of us had considered to be a bullet which is not permitted in civilised warfare.

THE PROTECTION OF THE HEART IN BATTLE.

Some members of our profession have for years advocated the wearing of a steel breastplate for the protection of the heart in battle, but I am afraid that the experience gained in this war with small-bore rifles is likely to damp their ardour in advocating the use of such a protective appliance. A man is as likely to be shot through the heart by a bullet entering at the shoulder, the side, the back, the loin, or even the head, as he is to be killed by a bullet entering in front of his chest. In fact, from all accounts I think that in this war the left breast was the least likely spot to reach the Boer's heart by a bullet on account of his assuming the prone position behind cover or protecting his chest in a trench. A man of Brabant's Horse had a narrow escape of being shot through his heart *viâ* his right ilium. He had just eaten a whole Maconochie ration and had started up the side of a kopje immediately afterwards. Some Boers had managed to get round the hill and were hiding in a mealie-field; they fired and the bullet entered the trooper's body at about two inches below the crest of the right ilium and came out immediately below the costal margin of the left eighth rib, probably having traversed his full stomach.

CONCLUSION.

In conclusion, I again wish to emphasise the opinion that the *vis medicatrix naturæ* of the old school will be found in a more prominent and exalted place amongst the methods and means of treatment in penetrating gunshot wounds of the abdomen than it has been since the birth of the new operative school a few years ago.

On board Royal Mail Steamer Saxon, Oct. 17th

NOTES FROM SOUTH AFRICA.

(FROM OUR TRAVELLING CORRESPONDENT.)

My last letter was written *en route* between Norval's Pont (Orange river) and Kroonstad. At Kroonstad I have been obliged to stop for a day, but I hope to leave for Pretoria to-morrow and thence to take a run down to Durban.

The small stations on the line between Bloemfontein and Kroonstad—Glen, Karee siding, Vet river, Smaldeel, and Ventersburg road—have each a civil medical officer in charge, with a small marquee hospital of from 10 to 30 beds. Here trivial cases are treated till the men are fit for duty, while serious cases, which are very few and far between, are sent down the line in ambulance trains to Bloemfontein. Winburg, some 20 miles from Smaldeel, with which it com- [illegible] hospital of 150 beds [illegible] er Major Hamilton, [illegible] has been the medical centre of a large tract of country—the Ficksburg, Bethlehem, and Senekal districts—which was for several weeks the scene of constant fighting with small marauding bands of the enemy.

The whole country between Bloemfontein and Kroonstad is inexpressibly dreary—wide stretches of sandy veldt sparsely dotted with kopjes and to all appearance unpopulated. September is the windy month in South Africa and our journey up was made in the teeth of violent sandstorms. The hot weather is now setting in, and the flies constitute a veritable plague. It is difficult to exaggerate the potentiality of these pests to spread infectious diseases, and all medical observers of the typhoid fever epidemic in Bloemfontein last spring are agreed in believing that flies were an important agency in spreading the disease. Mosquitoes are common enough in houses, but they are practically unknown in camps. I have caught several specimens, but have not yet seen the anopheles claviger or malaria-bearing variety.

Kroonstad is a miserable little town of tin-roofed houses straggling from the eastern side of the railway station to the Valsch river Streets alternate with waste plots given over to Kaffirs, empty tins, and general rubbish. Close to the station is the tiny hotel, now converted into a neat little hospital for officers, of whom there were four, who were convalescents, waiting there for a hospital train at my visit. Near the hotel is the church, a tin-roofed building with a wooden floor. Both these buildings were used for the temporary reception of sick soldiers when Kroonstad was first occupied and both were the subject of unfavourable comment by Mr. W. Burdett Coutts who appeared to think that beds should have been sent into the town for the reception of patients before our forces occupied it.

In marked contrast to the sordid, dreary little town are the camps on the western side of the station—No. 3 General Hospital, the Scottish Hospital, and the convalescent camp attached to No. 3 General Hospital. All these are close together and occupy an excellent site on a gentle eminence sloping down to the line. No. 3 General Hospital is a typical example of the best class of marquee hospital The lines are laid out with marvellous accuracy, the interiors of the marquees are neat and cheerful, and the patients appeared to have every comfort, including large double recreation and dining tents for convalescents. A grim reminder of war is the bomb-proof shelter between the hospital and the line, and it is not so long since that convalescent patients had to man the trenches in view of an expected attack by the notorious De Wet. Near to No. 3 General Hospital, but separated from it by the convalescent camp, is the Scottish Hospital, which consists of 20 tortoise tents which accommodate 200 patients, with several wooden huts used as administrative buildings. The general plan of the hospital is lacking in the symmetry and severe simplicity conspicuous in purely military hospitals, but the wards are cheerful and neatly kept, and nothing that human ingenuity could devise for the actual care and comfort of the sick has been forgotten. The services of the surgeons of this hospital have been requisitioned for an unusually large proportion of serious surgical cases, and they have been markedly successful in cases of intestinal suture and resection. I understand that this hospital has just been handed over to the Government, and I only hope that the services of some at least of its brilliant staff have been retained. Both of these hospitals have many vacant beds; in fact, the hospital arrangements all through South Africa—calculated as they are for a fighting army in an unhealthy country—are on far too lavish a scale for present circumstances, and the medical officers and the nurses everywhere report a lack of work.

Kroonstad, Sept. 28th.

WATER-SUPPLY IN SOUTH AFRICAN TOWNS.

(FROM A CORRESPONDENT.)

THE following notes, which we have received from a correspondent well situated for knowing what he is writing about, show that the question of water-supply in South Africa is still in its infancy and that drainage schemes as yet hardly exist.

CAPE COLONY.

Cape Town possesses a gravitation supply under the control of the corporation. There are two large reservoirs on Table Mountain to collect the rain, of which there are as much as 100 inches in the year. The neighbourhood of the reservoirs is jealously guarded and is free from all possibility of human contamination. This town is the only one in South Africa which is thoroughly drained.

Among the suburbs we have Wynberg, which also gets its supply from Table Mountain. Here there are two reservoirs and the authorities are considering the question of drainage. At Rondebosch and Claremont there is a spring water-supply, but it is not sufficient for the rapidly-increasing number of residents, and is recognised as being imperfect, so that a new scheme is under consideration, but there is as yet no drainage. At Kalk Bay there is a gravitation supply from reservoirs, without drainage. At Simonstown there is a water-supply from the mountain for naval and military purposes and in the town there is a storage reservoir from surface springs, but no drainage. At Burgersdorp there is a gravitation supply from springs five miles away across undulating country, while at Somerset East there is again a gravitation supply in addition to an irrigation supply, because water is collected in a catchment area in the hills and allowed to run down to the town in irrigation channels. At Caledon there is a gravitation supply, with a reservoir and a catchment area on the hill, all very good in spite of the absence of drainage. At Port Elizabeth, a town which has the distinction of being already half-drained, there is a gravitation and pumping supply of water from a catchment area situated in the hills 18 miles away from the town. Here there is a filter-bed from which the water flows in covered pipes to one of the most enterprising towns in South Africa. At East London there is a similar excellent water-supply but no attempt at drainage.

ORANGE RIVER COLONY.

The only town in this colony boasting of a water-supply is the well-known capital, Bloemfontein, where there is a pumping supply from the Modder river, 22 miles away, where the water is filtered and then pumped into the town. Now the Orange Free Staters were driven unwillingly to the expense of new waterworks because the town suffered so much every year from enteric fever. The town takes its name from Bloomfountain, a spring in the centre of the town, which though once considered to be perfect has of late years become more and more contaminated by the filthy habits of the people, by neighbouring cesspools, and by the complete absence of all drainage.

When the British so unfortunately allowed the Boers to repossess themselves of the Bloemfontein waterworks it was from the condemned springs in the middle of the town that our army was obliged to draw its drinking water. It will be remembered that the British entered Bloemfontein on March 13th, bringing with them numbers of young soldiers who were already harbouring the seeds of enteric fever contracted from the polluted water of Paardeberg and other camps. The troops were still fatigued after Cronje's surrender on Feb. 27th and the ensuing forced marches, and the bridges behind the advancing army had been destroyed by the enemy, so that it was impossible to get up a sufficiency of food, much less Berkefeld or Pasteur filters. Moreover, in the complete absence of fuel and with stringent orders not to interfere with the residents, it was impossible to boil the men's drinking water. Added to all this there came unfortunately at this time some heavy rain which must have washed much surface-dust and many typhoid bacilli into the drinking wells. To complete the picture, it must be remembered that the army had not had time to erect latrines and that the rain showers had every opportunity of washing the bacilli into the wells where everything necessary existed for the production of artificial cultures.

Assuming that these various causes aided, with others, in producing the typhoid fever epidemic the concentration of the poison at Bloemfontein was to be expected about the end of March, and allowing for two weeks' incubation and three or four weeks' illness the death-rate from disease in South Africa would presumably mount up about the middle of May. As a matter of fact, the death-rate from disease reached the high figure of 206 in the week ending April 28th and rose to 311 in the week ending May 19th, while it reached its maximum of 369 in the following week. I have gone into some detail on this point because it has always seemed to me that the chief defence of the Royal Army Medical Corps with regard to the typhoid fever epidemic at Bloemfontein might be the carelessness of the authorities who permitted the Boers to take possession of the only waterworks in the Orange Free State.

Is it too much to hope that some day a general officer while invading the enemy's territory will inform himself of the water-supply of any town which he is attacking and safeguard it at all costs? During the present war this would have been extremely easy, for the headquarters staff could have obtained all information from one or both of the two water engineers who have constructed most of the waterworks mentioned in this article.

THE TRANSVAAL.

Johannesburg possesses a water supply which comes from a farm 22 miles outside the town, shafts being sunk 18 feet into the dolomite limestone rock, and the daily yield is 1,000,000 gallons. This belongs to a private company. Johannesburg has no drainage yet, the daily removal-bucket system being in full force, worked by Kaffir coolies who are obliged to live in a special part of the town. The Johannesburg waterworks have more than once been nearly captured by the Boers since our occupation of the town.

Pretoria, although the capital, is a much smaller and less important town, and possesses a very excellent water-supply, though it is wholly dependent for drainage on buckets and Kaffirs. The water comes from a spring situated in a picturesque ravine between two of the hills commanding the town, upon the summits of which are built the empty forts which were supposed to defend the capital. There seems no possibility of pollution, for there is only one farmhouse near by and both the intake and the pipes to the town are well protected. Chemical and bacteriological analysis were very favourable in August, when examined by Dr. G. Turner, the medical officer of health of Cape Town, who has now been lent to the Transvaal. Moreover, the quantity of water is quite enough for 50,000 people and therefore it is ample for the 15 000 inhabitants of Pretoria.

Cape Town, September, 1900.

ASYLUM REPORTS.

Dorset County Asylum (Annual Report for 1899).—The average number of patients resident in the institution during the year amounted to 718 and comprised 349 males and 369 females. 115 patients were admitted during the year—viz., 54 males and 61 females. Of the 115 patients 96—viz., 48 males and 48 females—were first admissions, the remaining 19 being re-admissions. Dr. P. W. Macdonald, the medical superintendent, states in his report regarding the character of the admissions that there have been fewer cases of a melancholic type, but that those suffering from grave and organic forms of mental disease would seem to be on the increase. "Among the female admissions were numerous instances of an inexplicable mental breakdown after middle life and where at the time of the attack home comforts were not wanting. In these cases there is strong circumstantial evidence, that long-continued years of hard work under unfavourable and trying conditions had much to do with the subsequent illness." Cases of genuine epilepsy have been fewer among the admissions, and this is attributable to the increased efforts, mainly of a private and philanthropic nature, to treat and deal with epileptics in special homes. Of the juvenile admissions it is stated that in addition to the idiotic and epileptic there were also present general paralytics. "This dreaded and typical form of degenerative changes in the nervous system is, I regret to say, on the increase in this district." Almost 50 per cent. of the total admissions fell within the two decades of life from 20 to 30 years and from 40 to 50 years. Special interest is attached to the fact of this large proportion of cases drawn from the periods covering early manhood and the prime of life. "In the one case it reveals the strain on the mental faculties incidental to the start in life, and in the other the too oft-told tale of a breakdown after a prolonged struggle in the field of competition." An analysis of the ascertained causes of insanity among the patients admitted during the year gave the very large percentage of 37 as due to hereditary predisposition. "Each year brings fresh facts and further proofs of the widespread influence of heredity as a predisposing cause among the patients in this district." Mental anxiety and worry account for about 10 per cent. of the admissions and senile brain decay accounts for a similar proportion. In a large number of cases the actual attack was often brought on by a prolonged combination of causes. During the year 39 cases—viz., 18 males and 21 females—were discharged as recovered, or 5·4 per cent. of the average number resident The deaths during the year amounted to 41 cases—viz., 25 males and 16 females, or 5·7 per cent. of the average number resident. Among the deaths two were due to cardiac disease, three to chronic or acute renal disease, three to general paralysis, four to bronchitis, four to tuberculosis, pulmonary [illegible] and six to dysenteric and allie[illegible] unusual proportion of deaths f[illegible] referred to, it is pointed out that these deaths occurred at a time when the asylum was overcrowded, and rightly or wrongly this was looked upon as the most probable cause of intestinal complaints ranking so high. "In the annual report of the Commissioners in Lunacy for 1898–99 every asylum in which ulcerative diarrhœa, or so-called colitis or dysentery, had appeared has been bracketed insanitary." After a careful test of the drains of the asylum no defect, however, is said to have been found so that the cause of the prevalence of this disease remains unaccounted for. The proportion of tuberculous cases ending in death is regarded as small and is attributed to the good situation and the open air Bovine tuberculosis is also said to be comparatively rare in the south-west of England. The applications for the admission of private patients are greatly on the increase, and "it is much to be desired that no great delay will take place in providing separate accommodation for private patients." Electric light is now used in the building and the entire plant has continued to give satisfaction, the cost for the year ending March, 1900, being 1½*d* per unit The Lunacy Commissioners' report is not appended

Down District Asylum, Downpatrick (Annual Report for 1899).—The average population of the asylum during the year was 567 and consisted of 297 males and 270 females. The admissions throughout the year numbered 128—viz., 67 males and 61 females. Mr M J Nolan, the medical superintendent, states in his report that the admissions for the year were only two in excess of the number admitted in 1898. Of the admissions 19 presented no prospect of amelioration. As noted in the reports of previous years many of those admitted were advanced in years and broken down in health. "Such cases," adds Mr. Nolan, "are most unfavourable and cause much anxiety, as they require very special care in the hospital departments which, though accommodating over 100 patients, are barely able to meet the demands made upon them by the yearly increasing increment of senile and practically incurable cases." A history of heredity was ascertained in 34 per cent. and of alcoholism in 8 per cent. of those admitted. "The most remarkable feature of the admissions was the great frequency of heart disease with mental disorders, no less than 34 of the 128 cases admitted showing this association, and of those 34 18 were upwards of 60 years of age." During the year 60 patients were discharged as recovered, or 10 per cent. of the average number resident. A considerable number of those discharged as recovered were, in the first instance, handed over when convalescent to the care of their friends, and on the expiration of a probationary term of six weeks their names were finally removed from the asylum books. The deaths during the year amounted to 47—viz., 31 males and 16 females, or 8·3 per cent. of the average number in residence. Of the deaths four were due to apoplexy and paralysis, five to general paralysis, five to epilepsy, five to dysentery and diarrhœa, 10 to pulmonary phthisis, and 12 to cardiac disease. In no case was death due to suicide or misadventure. Mr. Nolan points out the value and importance of pathological investigation and urges that some coöperative scheme should be set on foot by the united Irish asylums to promote such research. Precautions are taken to guard against the contamination or spread of tuberculosis. Cattle on the farm discovered to be diseased were destroyed and the animals in which the tuberculin test gave rise to a suspicious reaction were isolated. "The milk-supply was recently specially analysed and found to be free from taint, so that the process of sterilisation is no longer necessary. The other prophylactic precautions reported last year have been continued and have been extended as far as possible." Dysentery and colitis still continue to make their appearance from time to time, though no local, hygienic, or dietetic cause can be found to account for its presence. "It is worthy of note that some of those who were attacked by the disorder had already suffered from one or more attacks of it in their own homes." The necessity for new buildings to accommodate the increasing number of patients is being steadily felt Mr. Nolan points out that the future development of building should not take the form of large featureless detention-wards, but that small, properly-equipped, classified, and self-contained blocks should take their place, and that the older portions of the existing building could be set aside for the accommodation of the chronic class. The farm department has been worked with benefit and with profit

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6139 births and 3860 deaths were registered during the week ending Oct. 27th. The annual rate of mortality in these towns, which had been 17·1 per 1000 in each of the two preceding weeks, rose to 17·3 last week. In London the death-rate was 15·9 per 1000, while it averaged 19·2 in the 32 provincial towns The lowest death-rates in these towns were 11·8 in Cardiff, 12·2 in Plymouth, 12·9 in Bradford, and 13·2 in Norwich; the highest rates were 20·8 in Swansea, 21·9 in Liverpool, 23·7 in Manchester, and 29·0 in Salford The 3860 deaths in these towns included 485 which were referred to the principal zymotic diseases, against numbers decreasing from 776 to 463 in the four preceding weeks; of these, 181 resulted from diarrhœa. 97 from diphtheria, 78 from "fever" (principally enteric), 45 from measles, 45 from whooping-cough, and 39 from scarlet fever No death from any of these diseases occurred last week in Plymouth; in the other towns they caused the lowest death rates in Norwich, Birkenhead, Halifax, and Newcastle; and the highest rates in Swansea, Wolverhampton, Salford, and Blackburn. The greatest often thought to be a date stone which had fallen into the pouch.

Those who know me never regard me as a "*laudator temporis acti*," and therefore, without any such feeling in the matter, I unhesitatingly state that no new fact or any development whatever with respect to appendicitis has been brought to light since the description of the disease more than half a century ago. The only novelties are a new name and a new treatment by the surgeon's knife. The name I dislike, as I have always considered that the nomenclature of disease should be clinical and not pathological. I trust that Mr. Littlewood will not view my remarks in the light of a criticism on his admirable essay but only as adding further to the history of a very interesting and important complaint. I am, Sirs, yours faithfully,

Grosvenor-street, W, Oct. 27th, 1900. SAMUEL WILKS.

THE ALLEGED EXISTENCE OF A "FOURTH DISEASE."

To the Editors of THE LANCET.

SIRS,—My attention has been called to an article by Dr. Clement Dukes, "On the Confusion of Two Different Diseases under the Name of Rubella (Rose-rash)."[1] In this article the writer claims to have established the proposition "on definite and analysed grounds that two clearly distinguishable diseases exist." The great importance of such a proposition demands much fuller criticism than the article in question appears to have received. None of your correspondents challenge Dr. Dukes's deductions and Sir William Broadbent even goes so far as to say that he accepts them "without hesitation." I venture, however, to think that the profession in general will require very much fuller investigation into such an admittedly difficult subject before it will be equally prepared to commit itself.

If we analyse Dr. Dukes's paper we find that he records three series of cases—(1) supposed "fourth disease" alone (16 cases); (2) scarlet fever concurrent with supposed "fourth disease" (31 cases); and (3) supposed "fourth disease" alone (19 cases), in which nine of the cases had had rose-rash on some previous occasion. On these three series Dr. Dukes bases his claim to have discovered a new disease. Let us take them separately. The first series of cases occurred in 1892. Dr. Dukes's diagnosis at the time was rose-rash of the scarlet fever variety. Eight years later he modifies his diagnosis and describes them as being the "fourth disease." No reasons for this are given, so for the sake of argument let us consider his original diagnosis as correct and regard them as having really been rose-rash.

The second series is the one to which Dr. Dukes attaches chief importance, and he considers that it alone is sufficient to establish the existence of the new disease. He says of it: "This epidemic proves incontestably that, besides scarlet fever, there is another malady, which I have provisionally named the 'fourth disease,' and that the one affords no protection against the other" This is a series of 31 cases in which seven boys had scarlet fever alone, 14 boys had supposed "fourth disease" alone, nine boys had scarlet fever shortly following supposed "fourth disease," and one boy had supposed "fourth disease" shortly following scarlet fever. Now, unfortunately, Dr. Dukes gives us very little information as to the clinical features of the supposed cases of "fourth disease" in this outbreak. He merely informs us that he was "summoned to a consultation on account of an epidemic which was regarded as the scarlatina variety of rose-rash (rubella)" No evidence whatever is adduced to prove that the cases were not rose-rash beyond Dr. Dukes's opinion to the contrary. Yet, although there is nothing at all inconsistent with the view that the epidemic was merely rose-rash concurrent with scarlet fever, we are expected to admit the existence of a new and hitherto unrecognised disease.

We now come to the third and last series of cases and here Dr. Dukes would strain our credulity to the uttermost This was an outbreak affecting 19 boys, beginning on March 19th, 1900, and ending on April 1st. According to Dr. Dukes this was "clearly an epidemic of the 'fourth disease' alone" He describes it as follows: "The illness resembled scarlet fever more closely than any other series of cases I have yet seen, due not only to the marvellous resemblance between the rash and that of scarlet fever, but also to the copious desquamation of the skin which in some instances succeeded."

In a *résumé* of the cases in this series we are told that the eruption "in nearly every case was very full and quite characteristic of scarlet fever. In fact, if ten experts had inspected the skin and made no other investigation all would have diagnosed the eruption as that of scarlet fever." The fauces were red and swollen. The temperature ranged from 99·4° to 104·2° F. The desquamation in some cases was very profuse, in one case the skin actually peeling off in sheets. The incubation period, one of the very few characteristics in which (according to the table given by Dr. Dukes) the "fourth disease" differs markedly from scarlet fever, *could not be ascertained in this series*. Lastly, not one of the 19 cases had previously had scarlet fever. Of the remaining points noted in connexion with this series there is not one at all inconsistent with the view, which I think most unbiased men will hold, that the outbreak was nothing more or less than simple scarlet fever. Dr. Dukes attaches importance to the fact that although the cases were sent home on April 3rd, the parents being informed that the epidemic was not scarlet fever, only one case came to his knowledge during the holidays which was diagnosed as scarlet fever. So far as this is positive evidence it supports the view that the cases were only scarlet fever, whilst in so far as it is negative evidence it proves nothing. This much is certain—that if this last series of cases is "fourth disease" there is not the least danger of the new malady being confused either with rose-rash or with measles. And yet Dr. Dukes tells us that it is what has hitherto been regarded as merely a variety of rose-rash and that children who are supposed to have had measles three times have really had English measles, German measles, and "fourth disease" Could anyone possibly mistake for measles or rose-rash such a disease as the one just described? Moreover, this last series of cases so closely resembling scarlet fever clearly differs very considerably from the first two series which resembled rose-rash; hence we can only conclude that there are two varieties of the new disease, differing from each other at least as much as the two varieties of rose-rash which Dr. Dukes has tried to split up.

There remains Dr. Dukes's table in which he sets forth the specific differences, as he sees them, between rose-rash, "the fourth disease," and scarlet fever. As regards the differentiation of the "fourth disease" from scarlet fever the principal point of distinction would appear to be that the incubation period in the former is from nine to 21 days, the same as in rose-rash, yet, as already pointed out, this important point of distinction was not ascertained in the last series of cases which so closely resembled scarlet fever. Another alleged distinction is that the duration of infectiousness in the "fourth disease" is only from 10 to 21 days. We may reasonably ask how Dr. Dukes has ascertained this with such a short experience of the disease. So, also, as regards the statement that its season is "spring and summer." Some stress is laid on the fact that the tongue, though it may be furred, is never a typical "strawberry" tongue. I think that most will agree with me that the typical "strawberry" tongue is too often absent in scarlet fever for much importance to be attached to its absence in a short series of cases. The alleged enlargement of the glands would at first appear of some importance, yet in another part of the paper Dr. Dukes says that in his experience "the lymphatic glands are always enlarged and tender whenever a copious eruption occurs on the skin *from any* disease." It would take too long, however, to criticise the various points seriatim. Most of them on examination will be found to be distinctions without any real difference; and, after all, the total number of cases of the supposed new disease on which the table must have been based is far too small for it to have much value. The first series, which occurred eight years ago and was diagnosed at the time as rose-rash, may fairly be excluded from the case, and the second series was so complicated with scarlet fever that many of the cases must have been valueless.

To briefly summarise, the weak points in Dr. Dukes's thesis are: 1. There is no proof that the first series of cases of supposed "fourth disease," diagnosed eight years ago as rose-rash, included anything other than rose-rash 2. There is no proof that the second series of cases of supposed "fourth disease," running concurrently with scarlet fever, included anything other than rose-rash concurrent with scarlet fever. 3. There is no proof that the third and last series of cases of supposed "fourth disease" included anything other than simple scarlet fever. Indeed, the evidence given points to its being so.

---

[1] THE LANCET, July 14th, 1900, p. 89.

It would be rash to deny the possibility of an unrecognised disease existing and closely resembling scarlet fever though distinct from rose-rash; but very much stronger proof must be forthcoming than any yet adduced by Dr. Dukes before it can be admitted that he has discovered and identified such a disease. I am, Sirs, yours faithfully,

C. Killick Millard, M.D., D.Sc. Edin.,
Late Medical Superintendent, Birmingham Fever Hospital.
Town Hall, Burton-on-Trent, Oct. 27th, 1900.

"MEDICAL SERVICE IN THE HIGHLANDS AND ISLANDS OF SCOTLAND."

To the Editors of The Lancet.

Sirs,—Poor-law medical officers in the highlands and islands of Scotland are again greatly indebted to you for your able and outspoken leading article in The Lancet of Oct. 20th (p. 1144). Could such an exposition find its way to our legislators our condition would probably soon be remedied. Our thanks are none the less due to Dr. William Bruce, than whom none knows our condition better, for his letter in The Lancet of the same date (p. 1163). He states the remedies clearly and practically, but with all respect to his wide experience and matured judgment I would like to comment on the following points. Regarding his second proposal there are no objections but the difficulty of getting the Government to pass a Bill in our favour, and to endeavour to obtain this is precisely our intention. Of course, parish councils will object, hence the futility of consulting them. One half of them [illegible] other half cannot see [illegible] unite to prevent us by [illegible] our rights. Poor-law medical officers have not been under the heel of parochial boards and parish councils all these years without fully estimating the latent possibilities of these gentlemen. The other and graver difficulty is the fact that only two or three men amongst us will have the whole fighting to do and have a host of parish councils against us, then the question arises, which will the Government believe?

Dr. Bruce says: "Seeing that the public at large really helps to pay for medical attendance to all and sundry in these parishes it ought to have its say in making and unmaking these appointments" Given an average parish of from 2000 to 3000 inhabitants with a pauper roll of, say, 70 and the payment to the medical officer *from the parish funds alone* on an average of £20 to £25 (which is only sufficient to keep his horse), ought these to have a say in the making and unmaking of appointments? A medical man receiving such a trifle is practically giving his services to that parish. I admit that he gets the other half of his salary from the medical relief grant and a precarious income from private practice, but with these the public at large (I mean the ratepayers of this said parishes) have nothing whatever to do. Even in private practice in these parishes a humane doctor cannot possibly charge what would remunerate him for his services. That trifling amount from the parish funds, besides partly remunerating him for attendance on paupers, has to cover attendance and medicine to all and sundry non-pauper—poor folk who cannot pay him. He has also to visit the different districts periodically, so that his services may be at the disposal of everyone. The above facts form the basis of our argument for an increased salary.

Regarding the suggestion that the Local Government inspecting officer would see justice done to the parish medical officer, I am afraid that during his summer trip to the highlands and islands he would be unable to settle disputes between parish councils and their medical officer; but how he could be constituted a judge of the professional competence or incompetence of a medical man either before or after his appointment by the parish is a question which, I think, admits of an obvious answer. I again offer my thanks to you and also to Dr Bruce for your ready sympathy and interest in our cause.—I am, Sirs, yours faithfully,

Henry Pearson Taylor, M.B., C.M Aberd.
Reafirth, Mid Yell, Shetland, Oct. 25th, 1900.

"AUTO-INFECTION THROUGH THE MOUTH A POSSIBLE CAUSE OF RELAPSES IN ENTERIC FEVER."

To the Editors of The Lancet.

Sirs,—I was much interested by Mr. G. W. Ord's letter on this subject in The Lancet of Oct. 13th (p. 1097). I not only agree with his views in this particular connexion but I am satisfied that physicians may trace many cases of self-poisoning in various infective diseases to the same source. Nay, more, I would go further, and add that I am satisfied, from experience, that an unhealthy state of the mouth is a fertile and very common cause of ill health. We are all agreed upon the importance of wholesome fresh air in contending with tuberculous and other cachexias from the poisonous effect of re-breathed air, sewer-gas, and the like. What, then, are we to anticipate when every breath which a patient draws is infected, more or less, by an unhealthy state of the mouth? Of latter years I have made it a habit to examine the mouths of all patients, and in a large proportion of cases I find quite enough there to account for bad health.

To give a single instance in illustration I will quote the case of a young man who was sent to me last year from the county of Wexford for advice about apprehended phthisis. This youth was in a very low and markedly marasmic state. On examining his chest I failed to detect any morbid change On bringing him over to the window to examine his mouth I found 14 carious teeth in the upper jaw, exhaling a fearful odour, which he was breathing day and night, and the secretion from which, with accompanying gumboils, he was constantly swallowing. I advised the removal of the teeth for the complete hygienic restoration of the mouth and I was not disappointed by the result which followed. The diseased teeth having been removed—painlessly under ether—the mouth was restored to a healthy condition, a set of artificial teeth replaced the diseased ones, and satisfactory mastication became possible. Within six months this youth was restored to health. This case is one of countless similar ones. Besides bad teeth we find many other morbid conditions of the mouth, the gums, ill-adjusted and non-removeable false teeth, suppurating alveolar abscesses, often painless, unhealthy conditions of the nasal and pharyngeal mucous membranes, a gross neglect of cleanliness, and so on, which mean, in fine, that the patient is breathing an infective atmosphere and swallowing poisonous secretions. If a lack of fresh air and the presence of sewer-gas and foul air in a dwelling-room are sufficient to poison a patient, what shall we say of such a condition as I described above? I am under the strong impression that this source of bad health is not sufficiently attended to in ever [illegible] re- fore I trespass on [illegible] to it I believe all [illegible] t I fear we are not sufficiently energetic in urging them on our patients. Others, younger than I am, may, I believe, with great advantage to the public health, work out the problem to which I now briefly allude.

I am, Sirs, yours faithfully,

F. R. Cruise, M.D. Dub.,
Consulting Physician to the Mater Misericordiæ Hospital, Dublin, and to the National Hospital for Consumption in Ireland.
Dublin, Oct. 24th, 1900.

AN ANOMALOUS SITUATION CREATED BY SECTION 4 OF THE INFECTIOUS DISEASE (PREVENTION) ACT, 1890.

To the Editors of The Lancet.

Sirs,—I venture to address you on a subject which I think may possess some interest for my brother medical officers of health—viz, the anomalous situation created by Section 4 of the Infectious Disease (Prevention) Act, 1890. This was brought prominently to my notice by an incident which occurred recently in my district. It came to my knowledge that a case of infectious disease (diphtheria) was existent at a dairy just outside the borough boundary. I immediately visited this dairy and upon inquiry I found that milk from it was being supplied in fair quantities to a retail milkseller as well as to private persons resident in this town; in fact, had it not been for my visit eight gallons of milk and 18 lb. of butter would have been sent into the town within an hour. I also found that the person in charge of the dairy was in direct contact with the sick person. I thus had every reason to suspect this milk as being likely to cause infectious disease within my district.

But by the Infectious Disease (Prevention) Act, although we as medical officers of health are empowered (on the order of a magistrate) to inspect any dairy if we are of opinion that infectious disease is caused, or is likely to be caused, in our district by milk supplied from such dairy, we can take no action, legally, to prevent the sale of this milk until infectious disease is (actually) caused.

Now, Sirs, this is where the anomalous situation is apparent: that we, who are appointed by law medical officers of health for the express purpose of preventing, as far as possible, the occurrence of disease are debarred, forsooth (by this same law) from taking any action until it has actually occurred! Surely this is the most perfect example of "locking the stable door after the horse has been stolen." I say nothing of the cumbersome and tardy method of procedure permitted us under this section, as I feel sure that every medical officer of health has his own system for overcoming this difficulty.

I am, Sirs, yours faithfully,
CHARLES H. RUSSELL,
Great Yarmouth, Oct. 28th, 1900. Medical Officer of Health.

"THE 'ANÆMIA OF DYSPEPSIA CONSEQUENT ON DIRT-EATING.'

To the Editors of THE LANCET.

SIRS,—Mr. A. J. B. Duprey's remarks on the above subject in THE LANCET of Oct. 27th (p. 1192) are most interesting. Dirt-eating, or geophagy, is a subject which has been mentioned by many travellers, but the dire results of this filthy habit have not been investigated with care by medical men. St. Lager is the only author to my knowledge who has attempted to collect any information on this matter and a short *résumé* of his remarks may be of interest to your readers. First, then, geophagy was observed by Humboldt to be prevalent amongst many Indian tribes, notably the Ottomacos, the women employed in potteries being the chief offenders. Auguste de Saint-Hilaire observed dirt-eaters in the interior of Brazil and also along the coast-line. De Castelnau noticed geophagy in the eastern portion of Bolivia. Cotting saw children eating dirt in the canton of Richmond, between Augusta and Savannah. He goes on to say that "they become pale, sicken, and die."

Geophagy has also been observed in the Antilles, in Jamaica, Hayti, Puerto Rico, St. Thomas, St. Martin, Guadaloupe, Martinique, St. Domingo, Guiana, Peru, Louisiana, Alabama, Georgia, Florida, and South Carolina. In Africa the habit has been observed among the deltas of the Senegal, in the islands of Los Idolos, and at Sierra Leone, and in other parts of the world, in Java, New Caledonia, New Zealand, and Siam. This pernicious habit, according to various observers, has frequently resulted in anæmia, marasmus, and ultimate death. The dirt consumed in most cases seems to be some kind of clay or marl; in several instances the earth forming the habitation of termites has been preferred. The habit became such a passion in certain victims that one observer records seeing muzzled slaves grovelling on the ground and attempting to inhale particles of dust. Hindoo and Chinese women have been known to eat meerschaum (*écume de mer*). In Guinea the negroes used to eat a yellow earth called *caouac* and became ill in consequence. In Java a ferruginous clay was sold in the public markets and consumed by purchasers. The clay used in New Zealand was a species of talcous schist in which copper was found. Another substance commonly partaken of in certain localities was native alum (*beurre de roche*); gypsum by others was used as an ingredient of bread—a custom not unknown to the modern baker! Geophagy is interesting also in connexion with endemic goitre. The drinking of certain muddy waters is associated with the incidence of goitre; for instance, Richardson, a companion of the unfortunate Franklin, noticed at Fort Edmonson, on the north branch of the Saskatchewan, that those who drank the muddy water of this river became goitrous. In other instances the drinking of mud-laden waters is not associated with goitre, which seems to prove that some particular earth or mineral causes goitre. It would be interesting if Mr. Duprey can tell us if goitre is found in any cases of dirt-eating that he has had to deal with.—I am, Sirs, yours faithfully,

LOUIS E. STEVENSON, M.B. Cantab., F.G.S.
Temple Sowerby, Penrith, Oct. 29th, 1900.

"THE ETIOLOGY OF RHEUMATIC FEVER."

To the Editors of THE LANCET.

SIRS,—We have read with care some letters published in THE LANCET of Sept. 29th (p. 970), Oct. 13th (p. 1098), and Oct. 27th (p. 1235), written by Mr. Lennox Browne, Mr. E. F. Grün, and Dr. Alfred Mantle respectively. These three letters dealt with points in our paper upon the Etiology of Rheumatic Fever, which was published in THE LANCET of Sept. 22nd (p. 861) and 29th (p. 932). To the letters of Mr. Lennox Browne and Mr. E. F. Grün we saw no reason to make reply except by private letters. To Dr. Mantle's letter in THE LANCET of Oct. 27th (p. 1235) we are compelled to reply in justice to him and in justice to ourselves. The tenour of each of the letters is the same—we have hardly done due credit to the writer's work upon this subject. In replying to Dr. Mantle we take the opportunity to acknowledge also the letters of Mr. Lennox Browne and Mr. Grün. In the first place it will be wise to state what claims we made for ourselves. They were two—the first, that as a result of an investigation, clinical, pathological, and bacteriological, supported by experiments made for us by Mr. H. G. Plimmer, we demonstrated that certain diplococci were *a* cause of rheumatic fever; the second, that we were, to the best of our knowledge, the first to demonstrate these diplococci in a rheumatic nodule. We are thus, fortunately, absolved from any errors of commission, though not from those of omission. Further we wrote as follows: "But we have started upon the assumption that it (i.e., rheumatic fever) is an infection, being led to this conclusion by the results of clinical and pathological experience and teaching," implying by these words that English teaching had led us to this assumption.

Mr. Lennox Browne claimed in his letter priority among "the moderns" for his insistence upon the association of rheumatic fever and tonsillitis. We do not intend to enter upon questions of priority, but it is clear from his published writings that he fully recognised the importance of this association. The recognition of this is, in our opinion, an important step in the history of the theory that rheumatic fever is due to an infection of microbic origin. Mr. E. F. Grün claimed that we had corroborated his observations as to the invariable presence of a specific organism in the blood of patients suffering from rheumatic fever. We entirely fail to see the truth of this. Diplococci were present, it is true, in the *cultures* made from the blood of two patients suffering from rheumatic pericarditis and we discovered them growing in chains in the media after incubation. We did not demonstrate them in blood films as Mr. Grün claims that he did. This point is, however, but a small one. Clearly, before we can give Mr. Grün any credit for his observations we must either see his preparations, or ourselves confirm his statements, or see a confirmation of them. One slide he kindly sent us certainly showed numerous diplococci and other organisms. It was, however, a sputum preparation, not a blood film, and therefore has no bearing upon this question.

To Dr. Mantle we owe an apology which we freely give. We were, to our regret, unaware of his researches and we briefly allude to them now. Dr. Mantle in the *British Medical Journal*, June 25th, 1887, wrote a paper upon the Etiology of Rheumatism considered from a bacterial point of view. From seven cases of this disease he obtained, with due precautions, fluid from the knee-joints and obtained growths upon gelatinised meat infusions. He also demonstrated bacteria in the blood in 16 more acute cases, some subacute cases, and 10 cases of rheumatism in childhood. The bacteria were a micrococcus occurring sometimes as a diplococcus and a small bacillus. Dr. Mantle demonstrated these organisms at the time of the reading of the paper and figured them in his paper. They throve best in an acid medium and their growth on the solid media gave "a pretty reticulated brown appearance." He also obtained each organism in pure culture. No experiments were made with animals, and Dr. Mantle expressly stated that these alone could decide the question of their specificity. There can be no doubt that in 1887 Dr. Mantle fully recognised the likelihood of rheumatic fever being due to an infection, and that he further carried out some important and laborious investigations in support of his contention. Most of our references to foreign workers were chosen because of the experimental work they had carried out, but had we been aware of Dr. Mantle's paper we should certainly have alluded to his researches.

One sentence in Dr. Mantle's letter we should like to interpret carefully. Dr. Mantle writes: "I am thankful to find that it has been now clearly demonstrated by the experiments of Dr. Poynton and Dr. Paine that the diplococci alone or with other micro-organisms are the cause of rheumatic fever and its complications." We believe we have demonstrated that a certain micro organism in the form of a diplococcus is *a* cause of rheumatic fever. Valvulitis, pericarditis, arthritis, tonsillitis, probably pleuritis and chorea, are manifestations, not complications, of rheumatic fever, and results of this diplococcal infection. Whether right or wrong the view has the merit of being definite and not complicated by the *question of secondary infections*, and it is the outcome of our investigation. We concluded that such bacilli as were present were not a cause of the disease. Whether or not the diplococci are the *only* cause of rheumatic fever we are not as yet in a position to state

We are, Sirs, yours faithfully,
F. JOHN POYNTON, M.D., M.R C P. Lond.,
Assistant Physician to the Hospital for Sick Children, Great Ormond-street,
ALEXANDER PAINE, M.D. Lond.,
Assistant Bacteriologist to St. Mary's Hospital, London.

THE DIAGNOSIS BETWEEN PERICARDIAL EFFUSION AND ENLARGED HEART.

To the Editors of THE LANCET.

SIRS,—Altho[illegible] r corrections to make to the [illegible] in 1896,[1] the importance of [illegible] may be obviated which are alw[illegible] as in the case of fatal punc[illegible]y Dr. Norman Moore,[2] disast[illegible] for re-stating facts not yet generally utilised. Independently of skiagraphy, any expert percussor can rapidly and safely identify an uncomplicated enlargement of the heart, or, on the other hand, a considerable effusion with or without [illegible]

over the right fifth interspace which was first insisted upon by Rotch, but is not in itself diagnostic. It consists in the sharp contrast between the outlines of dulness of a pericardial effusion and of the right border of the heart. The *posterior test* is even more reliable, as it is independent of the influence of partial agglutinations which sometimes exclude the fluid from the anterior corners of the pericardium. It is therefore essential that this test should not be misunderstood. The familiar infra-scapular patch of tubular breathing and ægophony to which Sir William Broadbent refers in his third edition[4] in connexion with my name is often set up, particularly in small chests, by a simple enlargement of the heart with compression and engorgement at the left base. This sign was put forward as merely confirmatory and not distinctive, and as "occurring also in pleural effusions." It is the other sign, the "lower dorsal dull patch," which is of practical use in difficult cases "The value of this sign is that, unlike many others, it is very sharply defined and does not fit any other diagnosis."[5] The almost median position of this dulness below the tenth rib, that is, below the vault of the diaphragm, its quadrilateral shape, and its extension to the spine and beyond it for one or two inches into the right chest render it quite unmistakable, unless it should be merged into the dulness of a double pleural effusion. I do not remember that any of the pupils to whom it has been demonstrated failed to recognise it; the failure of some of their first attempts to elicit it does not, of course, invalidate the test. I have examined for this characteristic dulness numerous cases of excessive enlargement of the heart, but always in vain, and I am satisfied that it cannot be produced by the latter. An actual demonstration to the contrary would therefore possess much value. As a fact, however, the dulness in question is not the dulness of the heart or of the fluid effusion, but is a dulness merely induced by the presence of fluid higher up The patch c[illegible] evel of the floor of the [illegible] by an enlarged heart.

Curzon street, W., Oct. 26th, 1900 WILLIAM EWART.

"THE CAUSE OF CARIES OF THE TEETH."

To the Editors of THE LANCET.

SIRS,—Mr. A. Berlyn's statement in THE LANCET of August 25th, 1900, p. 629, regarding the majority of South African natives, that "their only method of cleansing their teeth is to fill the mouth with water and rub the teeth with the finger," may be very true as applied to those natives who live in the towns. The typical "Red Kaffir" at home invariably after each meal rubs his teeth with a little of the cold wood-ash from [illegible] his mouth with water, a[illegible] account for the absence o[illegible] teeth. As to food, the "Red Kaffir" does not often eat "mealie meal" which, as a rule, he is obliged to buy, and "mealie meal" of his own manufacture bears little resemblance to th[illegible] ary food consists of [illegible] the "stamped mealie, [illegible] by means of pounding in a wooden mortar. In either case when cooked the resulting "porridge" is certainly soft to handle, but one finds it extremely glutinous and somewhat tough to masticate. During the "mealie" season the "green mealie"—the unripened "cob"—is greatly relished. These "cobs" are, as a rule, roasted at the side of the fire and though undoubtedly palatable are decidedly tough and require considerable mastication. In this portion of the country and in the native territories, too, I have often noticed a flattening and often actual cupping—caries apart—of the crown surfaces of the teeth, more particularly of the molars, and this not only in the Kaffir but also in those colonial born whites whose food has consisted mostly of "mealies." How long the native has cultivated the mealie seems somewhat uncertain. It is not mentioned by travellers in Africa before the sixteenth century, and though probably first imported from America I can find no mention of its introduction to this country. In 1687 a shipwrecked crew in Natal victualled a ship of their own construction with provisions purchased from the natives, and though Kaffir corn, salted and smoked meat, goats, fowls, and pumpkins are mentioned, the "mealie" is conspicuous by its absence Before civilisation overwhelmed him the "Red" rejoiced not only in his own flocks but in the risks and excitement of the chase, and skilled as he was in the use of his own weapons his larder was accordingly always well stocked with meat His love for meat still exists, but the inevitable "mealie" forms his staple food, and as long as there are "mealies" and Kaffirs the latter will continue to consume the former and maintain his fine teeth and well-formed jaw in the best of condition

I am, Sirs, yours faithfully,
THOMAS QUIRNEY M.R C S Eng, L R C.P. Lond.
Komgha, Cape Colony, Oct 6th, 1900.

THE DANGERS OF "TICKLERS."

To the Editors of THE LANCET.

SIRS,—Passing along the Strand yesterday (C I.V. day) I saw a peacock-feather-tip thrust into the eye of a person obviously suffering from purulent ophthalmia. Almost immediately thereafter the same feather tip was sent perilously near the healthy eyes of another person. Comment is needless; other diseases may possibly be conveyed in similar manner. Can nothing be done to suppress this dangerous nuisance?

I am, Sirs, yours faithfully,
ARTHUR J. HARRIES, M.D. Brux.

Adam-street, W.C., Oct. 30th, 1900

TENDER FOR CONTRACT BY MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—I enclose copy of letter received from the Castleford Urban District Council about attendance on cases at the infectious hospital, and I should be grateful for your opinion on the matter. Hitherto it has been the custom for each medical man to attend his own patients at the hospital and to make his own charges to the council. Personally, I feel it would be an unprofessional act to "tender" for an appointment in this way, and I propose to write to the council to this effect. I am, Sirs, yours faithfully,

Castleford, Oct. 30th, 1900. W. KEMP, M.B. Edin.

[COPY.]

Urban District Council Offices, Castleford, Yorks,
Oct. 29th, 1900

Re Cases at the Infectious Hospital

DEAR SIR,—I am instructed by this council to state that, in their opinion, the attendance of different medical practitioners at the hospital is, on several grounds, inadvisable, and that it would be better if one medical gentleman alone had the case [illegible] responsible for the payment of fees [illegible] patients desire to retain the services [illegible] they will be at liberty to do so, they [illegible] you if you will kindly give us your terms, including medicine and attendance, for cases of infectious diseases at the hospital.—Yours faithfully. H. H. BROADBENT (Clerk).

Dr. W. Kemp, Castleford.

*** The medical men of the district should meet and agree upon the course to be pursued. In this way a decision will be arrived at that is best for the community. We do not think it well that medical men should tender for contracts, and we are certain that where this method is employed the public will be badly served.—ED. L.

"ORTHOPTIC TREATMENT OF CONVERGENT SQUINT IN YOUNG CHILDREN": A CORRECTION.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to correct one or two errors in your notice of the paper read by me at the last meeting of the Ophthalmological Society?[1] The report says: "Mr. Worth ...... commonly commenced treatment as follows." This should be: "Treatment adopted by most surgeons was as follows." Again, "The visual acuity of the child's squinting eye was obtained." It will naturally occur to anyone that these small children cannot read Snellen's types. It should have been mentioned that I described a method by which the visual acuity might be ascertained. The report says: "Mr. Worth had found that this treatment in some hundreds of cases caused a disappearance of the squint, &c." What I said was that I had carried out the treatment in some hundreds of cases and in a considerable proportion it had caused a disappearance of the squint, &c.

I am, Sirs, yours faithfully,

Harley-street, W. CLAUD WORTH.

*** We regret the inaccuracy of the report.—ED. L.

THE MEDICAL DIRECTORY FOR 1901.

To the Editors of THE LANCET.

SIRS,—You have frequently been good enough to refer in your columns to the accuracy of the Medical Directory. As you are aware the Directory cannot be up to-date unless all the members of the profession and the secretaries of medical institutions respond to the editors' requests for information. All persons interested must now communicate with the editors at once, for in a few days it will be too late to attend to any further alterations.

We are, Sirs, your obedient servants,
J. & A. CHURCHILL.

Great Marlborough-street, W., Oct. 22nd, 1900.

THE TEACHING OF HISTOLOGY, ETC., AT ST. ANDREWS UNIVERSITY.

To the Editors of THE LANCET.

SIRS,—I would like to point out a slight inaccuracy, or rather omission, which occurs in your table of classes on page 689 of THE LANCET of Sept. 1st, 1900, which has been brought under my notice. It would appear from this list that I only teach in summer and do not teach histology. I give in winter (1) a full junior course of 100 meetings, (2) a senior (lecture) course of 40 to 50 meetings, and (3) a senior practical course of 50 meetings; and in summer (1) a course of 50 meetings of histology and physiological chemistry and (2) lectures on development and reproduction (see pages 164–166, Calendar, 1900–1901, St. Andrews University). I think your otherwise excellent list hardly represents my classes correctly. I am, Sirs, yours faithfully,

D. FRASER HARRIS.

University of St Andrews, Oct. 23rd, 1900.

"THE SPAS OF CENTRAL WALES."

To the Editors of THE LANCET.

SIRS,—I am sure that much real good would be done and much valuable instruction gained in the field of hydrotherapeutics if the excellent suggestion of Mr. T. Garrett Horder in THE LANCET of Oct. 20th (p. 1176) could be carried out. I am pretty certain that the majority of our profession are quite ignorant of the sound inducements which are offered by our spas at home. These spas would become better known to the profession and their merits could be sifted therapeutically if the Balneological Society would adopt the suggestion of Mr. Garrett Horder and visit the various spas in this country. He speaks of the beauties of Central Wales and the remarkably bracing effects of the beautiful elevations of that district. He did not speak of the medicinal value of the waters found there. Yet if he will refer to the analyses of these waters and to the clinical records concerning them he will find that we possess near at hand means not excelled by those of any Continental resort of treating patients by a course of waters internally and externally. In the district of which he speaks there are three more or less well-known spas—namely, Llandrindod, Llangammarch, and Llanwrtyd. The first has its sulphur and saline springs, the second its barium and saline waters, and the third its waters like Harrogate. Llangammarch is right in the centre of this beautiful elevated district; it is charmingly situated and enjoys most invigorating air. The hotel is high up and just under the imposing shelter of the Eppynt range (1800 feet). In the *British Medical Journal* of Oct. 20th Dr. Robert Saundby, speaking of Llandrindod, which is close to Llangammarch but not so prettily situated, says that it owes more to its altitude and climate than to the waters, and on this account is so satisfactory in the treatment of nervous exhaustion, dyspepsia, and gout. Quite recently you, Sirs, drew our attention to[1] the iron waters of Shanklin Spa, and at the risk of trespassing on your space I cannot help repeating the valuable opening remarks you made in that article. "In spite of representations to the contrary English people still visit the various spas of the continent, whatever may be the advantages which may be had at similar places in this country. Fashion is doubtless the chief factor which has hitherto been unfavourable to enterprise in regard to the development of English spas. Yet if a list of the natural springs of Great Britain be consulted it will be found that almost all kinds of mineral waters occur in this country. We have thermal baths at Bath, sulphur waters at Harrogate and Llanwrtyd in Wales, and saline springs and barium springs in Wales, not to speak of the chalybeate springs at Tunbridge Wells, Brighton, and elsewhere. In some instances, of course, great efforts have been made to equip these places on a scale similar to Homburg, Wiesbaden, and Schwalbach on the continent, but our home resorts do not possess the renown of the foreign spas. Individual enterprise has done what it could but patronage has failed." I venture to think that the Balneological Society would earn the gratitude of the whole profession by bringing before it the undoubted merits of our own spas in the way Mr. Garrett Horder has wisely suggested. I inclose my card

"THE ROYAL ARMY MEDICAL CORPS: 'THE REASON WHY.'"

To the Editors of THE LANCET.

SIRS,—"Deadly Seniority's" letter in THE LANCET of Oct. 27th will hardly commend itself at the present moment to officers of the above overworked corps Is this an opportune moment, when every officer of the corps has been working at high pressure and conspicuous zeal, for "Deadly Seniority" to advocate increased burdens being laid on their shoulders? Rather, I should think, it is time for the authorities to look about them for some means of making the corps more popular among the rising young medical men of the day. It is all very well to advocate extra examinations and increased "special instruction" classes, but when men are laying down their lives on the battle field [illegible] will last them the remainder of [illegible] home at ease" like "Deadly Seniority" would serve a better purpose and do more for the well-being of their military *confrères* if they tried to lessen, instead of augmenting, a burden which has proved a great deal too much as it is at present for a great number of officers. The classing of lieutenants of the Royal Army Medical Corps with the subalterns of a line or cavalry regiment as regards their knowledge of the special duties of their corps shows how little "Deadly Seniority" can know of the actual working of the Royal Army Medical Corps, where the knowledge of their professional work is the first and the routine of military work the second point to be considered.

I am, Sirs, yours faithfully,

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Great Increase of Plague in India.—Cholera in Kashmir.—Decrease in the Famine.—The Success of the Pasteur Institute.—Famine and Vitality: A Problem

A FURTHER serious rise has occurred in the mortality from plague throughout India—viz, from 1442 deaths for last week to 2136 deaths for the past seven days. The Bombay Presidency reports 1215 deaths, Bombay city 87, Bengal Presidency 33, Calcutta 104, and the Mysore State 696. The increase seems to be pretty general. Poona is once again in the throes of a severe outbreak, and is having from 60 to 80 deaths from plague every day. Up to a recent date the disease was confined to the city, but within the last few days indigenous cases have been discovered in the cantonment. It will be remembered that the first outbreak in Poona occurred in the first three months of 1897, the second occurred in the last four months of the same year, the third occurred in the monsoon months of 1899, and now the fourth is developing at about the same period of the year as the second in 1897. All seasons have thus been represented with the exception of the hottest months. Plague seems to be rising in Calcutta, while the returns for Bombay city show an ominous fluctuation In Mysore city there are over 100 cases daily. This general increase is very ominous Just as a local outbreak develops slowly for some time before the almost sudden explosion of virulence [illegible] or trebles the mortality, so this [illegible] from plague in so many different [illegible] howing a concurrent development of the disease at several centres, may be expected to assume alarming proportions at a later period. The present recrudescence commenced in Mysore and some of the towns in the Southern Mahratta country, and while the local outbreaks were reaching their height it has been commencing in Poona Presently renewed activity in Calcutta and Bombay may be looked for There are already indications in both cities of a recrudescence of the disease. The general mortality in Bombay city keeps inordinately high. Last week 1026 deaths were returned, and there has been a slight rise to 1043 for the past seven days. Of these 86 were plague and 54 were cholera, so that the excess of over 300 has to be accounted for. Diseases of the digestive system are abnormally prevalent and there are large excesses in the deaths from phthisis and other lung diseases. The situation is unsatisfactory.

The sudden increase in the mortality in Calcutta which has followed the floods (of Sept 19th to 22nd) which I reported last week still continues and the daily death-roll is about double in size While cholera, diarrhœa, and dysentery explain a large proportion of these deaths there are others which remain [illegible] The cases returned in the [illegible] have increased, but there a [illegible] tily accounted for. Relapses of malaria from exposure, &c, may explain many deaths, as it is hardly likely that plague would take on such a sudden development. So few natives are really seen during their illness that the diagnosis from reports after death is exceedingly difficult. The increased mortality occurred at first in the suburban districts, but it has since taken place all over the city. The worst-drained and the most malarious districts suffered most.

Cholera still continues severe in Kashmir, where up to Sept 30th there have been 4634 cases and 2379 deaths.

A drop of nearly another 500,000 is reported this week in the numbers under famine relief, the total for the whole of India being now just over 3 000,000, of whom 693,000 are on relief works and the remainder are receiving gratuitous relief.

The Pasteur Institute at Kasauli under Major Semple, R A M.C., is being sought after by all classes. The total number of patients to date is 52—viz., British officers, 7; soldiers, 22; native officers, 1; sepoys, 3; European civilians, 5; and natives, 14 Two Brahmins have commenced the treatment, which may be taken as an indication that high-caste natives are not averse to taking advantage of the institute.

Some curious results are brought out by a comparison of the vital statistics of the North-west Provinces and Central Provinces for the year following the last famine Both provinces suffered severely from the famine in 1897, but with returning prosperity the increase of births was remarkable. The year ending in 1899 showed a still higher birth-rate. It is said that the districts which suffered most show the rise above the mean rate. This increased birth-rate after famine times has been observed before. The question is whether the cause is physical or social It may mean that large numbers of marriages which had been temporarily postponed took place with the earliest signs of returning prosperity. On the other hand, the cause may be physiological and may be an effort of nature, so to speak, to replace the loss caused by the famine This has its analogy in the animal and vegetable kingdoms. Increase of food-supply does not necessarily increase the population and many plants are known to seed better on a poor soil than on a rich one. The increased birth-rate of these two provinces was accompanied by a great rise in infantile mortality Notwithstanding the famine and the high infantile mortality the population has increased by 700,000, whereas in ordinary years the deaths almost equal the births and the population has been nearly stationary According to this generalisation next year ought to see a great increase of population (by a great number of births) in all those districts affected by the terrible famine of the present year.

Oct. 4th

BLACK-BEETLES AND LODGINGS.—At the Paignton (Devon) County-court on Oct 22nd a lodging-house keeper sued a gentleman for £9 for rent of furnished apartments. Evidence showed that the defendant had engaged the rooms for three weeks from July 14th, but that owing to the prevalence of black-beetles in the bedroom he left after three days. He, however, offered to pay for the three days' use of the rooms The plaintiff's case was that the rooms were reasonably fit for habitation His Honour (Judge Edge) held that any person taking a lodging and finding black-beetles there would be justified in leaving and gave judgment for the defendant with costs

THE UNIVERSAL EXHIBITION OF PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

(Continued from p. 1239.)

THE FOREIGN AND BRITISH SANITARY SECTIONS.

The British Sanitary Section.

IN the British section there is only one stove, that of Messrs. Musgrave, the well-known Belfast firm. In view of the numerous accidents that have happened this firm will not consent to manufacture a portable stove, and further they have now a special air inlet so that fresh air may be mixed with the products of combustion and thus help to oxidise them. It is in the artistic decoration of the stoves rather than in any very recent improvement of construction that this exhibit has made its mark. Further, it is satisfactory to note that these British stoves are much appreciated and largely sold in France, where the method of economic warming by means of stoves instead of open fires has been much more studied and utilised than in England. The largest of all the exhibits is that of Messrs. Doulton and Co. who as members of the jury are *hors concours* They have two very artistic fire-places made of Doulton ware with slow combustion grates. So much has already been done in respect to the construction of closets and urinals that it is difficult to improve upon the models that are almost perfect, yet in respect to urinals there is a new method of draining them in an open glazed channel which is only covered over with brass grating. There are, therefore, no small pipes and pipe fittings. This means less labour and less chance of a stoppage and consequent nuisance. The water travels in the open till it reaches the gully or trap at the end of the row of urinals. Everything can thus be readily cleaned and those bugbears of urinals, cigar ends, can be dealt with in a summary fashion. Also, instead of the water being delivered all round the top of the urinal it is now discharged in the centre of a spreader or disc placed in front of the pipe. The water is equally and well distributed and this is a simplification in regard to fittings An asylum closet is shown where there is no sharp edge, angle, or hook, and no chain or string, by which the patient might injure himself. Then there is a bath with a rim around it so contrived that water cannot splash out of it. The outside also as well as the inside is enamelled, and this preserves the metal which is apt to be injured by the action of the atmosphere, especially at the seaside. For a hospital washstand and to prevent the risk of overflow the water is turned on by pressing a pedal with the foot, but after a moment a self-regulating valve shuts off the water. If more is required the pedal must be pressed again. Then to a hospital bottle and pan-washer a glass lid is affixed, which when raised produces a flush that automatically washes out the pan. Also there is a gulley which can be opened for cleansing purposes by removing only two screws and access is then gained to the top of the trap

Opposite Messrs. Doulton's exhibits there are Blackman's well-known ventilating screw fans and Boyle's equally well-known exhaust cowls. Close by Jeyes's Perfect Purifier is the only disinfectant shown in this section.

Mr. George Jennings who has received the highest award—namely, the "Grand Prix"—also makes a very large display of his well-known and excellent sanitary apparatus. He has likewise public urinals with no piping but open channels instead. Then there is a very ingenious urinal for domestic purposes which is closed over by a door; when the door is opened it causes a flush of water, and when closed it looks like an ornamental cupboard. There are some special closets for asylums and railway stations, so contrived that the flushing gear cannot be injured by mischievous or rough treatment. Close by there is a closet pan the porcelain part of which rises about a foot above the back of the seat. The latter has a counter-weight so that it is always raised unless purposely pressed down. When the seat is raised the pan forms at once a urinal and a receptacle for slops. Of course, the same may be said of any closet where the seat can be raised, but in this case the risk of spilling water on the floor is less likely to occur as the back of the pan rises considerably above the level of the seat. There are also some washstands which on tilting the basin disclose a urinal underneath and at the same time the raising of the basin flushes the urinal. Finally, I noticed a closet pump for yachts and other ships, where the force of the pump is arranged so that the contents drawn from the pan of the closet are propelled to some distance from the ship.

Another large exhibit is that of the Établissements Porcher which have the monopoly for the sale in France of the sanitary hardware manufactured by Messrs. Brown, Westhead, Moore, and Co. This exhibit is interesting because it shows us that some 20 years ago there were practically no French manufacturers who produced sanitary closets. Nothing that was then made could prevent the passage of sewer air or automatically insure anything approaching to cleanliness. Such closet pans as existed had to be cleaned with the aid of a brush; an effective flush was unknown. Therefore, the few really sanitary closets that were placed in French houses had at first to be imported from England. Hence to this day the French Porcher Company import largely English goods and therefore exhibit their closets in the British section, for in the main they are of British manufacture though some of the fittings are of French make. The chief feature in the latter is that they have contrived to attach the wooden seat and even the wooden lid to the hardware pan instead of being fixed to the wall behind the pan. One pan is provided with a double syphon and this when the water is discharged produces a momentary vacuum between the two syphons, so that the water is drawn by suction instead of being merely propelled out of the pan. It would require a lengthy series of experiments to judge whether this is an advantage.

The Dutch and Austrian Sections.

Leaving the British section there is a small compartment close to the German section where the Dutch give some information as to the sanitary administration of Holland. For instance, there are photographs of all the sanitary offices at Amsterdam, of the system of disinfecting, and showing how a house is declared to be infected by a notice affixed to the door so that no one can enter unaware of the danger incurred. Then comes the Austrian section which though very small attracts some attention because there is a wax model, life-size, of a calf during the process of collecting vaccine lymph. The precautions taken and the sterilised dressing to protect the vaccinated parts are all displayed in a manner that should dispel whatever apprehension may still remain in regard to vaccination. Very fine coloured maps indicate the distribution of diseases in different parts of the Austrian Empire and there are the exhibits of various institutions and sanatoria, especially for children, but there is nothing in regard to drainage, ventilation, or sanitary engineering.

The Russian Section and the Jenner Memorial.

The Russian sanitary section occupies a very large space, a great portion of which is taken up by wax models. Some of these come from the St. Petersburg Museum of First Help. They are life-size models of accidents to various parts of the body and they show how hæmorrhage may be stopped and temporary dressings made in the absence of, or while waiting for, surgical aid. This is a somewhat ghastly display; it does not fail to attract a large crowd and calls forth many expressions of commiseration. The question is whether many people try to engrave upon their minds the indications given and will remember what to do under similar emergencies. Under the auspices of the Russian Society for the Protection of Public Health, which is patronised by the Government, a public culinary school has been formed and it exhibits wax models of various sorts of meat and of vegetables in both healthy and unhealthy conditions. There are also many other articles, such as coffee and every substitute used for coffee, torrefied maize, wheat, chicory, &c.; in fact, there is here a complete museum of domestic economy. Close by there is a large exhibit of the Russian Red Cross Society. It consists of a field ambulance which has not only a hospital tent, an operating tent, a portable pharmacy, and sterilisers for bandages and instruments, but also a kitchen with all the cooking utensils and all the tools necessary for mending any object belonging to the ambulance. Only a very small compartment of the Russian section is reserved to private exhibitors. Here there is a sort of cupboard with wire arrangements for keeping books open so that they may be disinfected. Then there is a domestic filter, just a simple sandstone to clarify the water, but below inside the pedestal on which the filter is placed is an electric pile, the electrolytic gases produced thereby being said to exert a purifying action on the water.

What, however, will interest English visitors most is a handsomely decorated compartment which may be described as the Jenner exhibit. This has been the work of Professor Hubert, physician for the children of the poor and secretary of the Russian Society for the Protection of Public Health. This exhibit is a veritable history of vaccination, especially in so far as Jenner himself was concerned. In the centre there is a picture of one of Jenner's first experiments in vaccination; then there are several manuscript letters written by Jenner and four of his own coloured drawings of vaccine pustules. One wall is covered with all manner of caricatures and other prints published when first the question of vaccination began to agitate the public mind In one case there is the brevet by which Alexander Aspénny was promoted to the rank of sub-lieutenant because he was the first to consent to be vaccinated. This original document bears the signature of Catherine II. and the date of 1768. Jenner's answer, written in 1802, to a letter which he had received from the Empress Maria Feodorowa is likewise shown, as is a collection of medals struck in commemoration of important events in regard to vaccination. There are many drawings and wax models of healthy and of abnormal pustules, and though most of these things are purely historical the latest innovations are also exhibited. Thus what constitutes an entire room is devoted in the main to relics recalling the great work done by Jenner, and these, which have been collected by a Russian, form part of the Russian section. Nowhere in the British sanitary section is any sort of honour rendered to any one of the many Englishmen who, like Jenner, have largely contributed to benefit humanity by initiating some important sanitary reform.

Paris, Oct. 29th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Hospital Sunday Fund.

FOR more than 40 years a special appeal has been made annually at the various places of worship in Birmingham and its suburbs on behalf of the hospitals and allied institutions for the relief of suffering. It has been customary since the movement was started to present the full amount collected to the General Hospital one year, the next year to the Queen's Hospital, and the third to the amalgamated charities, some 16 in number. Sunday, Oct 28th, gave an opportunity of repeating this valuable effort. In spite of adverse weather and so many outside calls upon the pockets of the benevolent it is satisfactory to record a ready response to the appeals made. Up to the present time the amount collected has reached the sum of £4000 odd.

The Hospital Saturday Fund.

A worthy sister of the above movement, one which has exceeded it considerably in dimensions and to some extent in interest also, is the Hospital Saturday Fund. A meeting of the delegates was held on Oct 23rd when cheques were distributed by the Lord Mayor to the various medical charities participating in the proceeds. It was announced that the collections up to date amounted to £18 204 12*s* 8*d*., beating the record of last year by £73 The chairman stated that they would like to increase the amount of the cheques to the various institutions, but that they had other liabilities which had to be met. They had made improvements alone costing £4000 at the Tyn-y-Coed Convalescent Home. The systematic collections made from the manufactories enabled this method to assume large proportions and to be so successful. Cheques amounting to £10,000 were then distributed to different medical charities in proportion to their size and needs and votes of thanks were passed to those who had given so much time and labour to the details connected with the scheme.

The Midland Medical Society.

The inaugural meeting of this society for the session 1900–1901 was held at the Grand Hotel on Oct 26th. A large number of members and visitors assembled to hear an address given by Professor Alexander R. Simpson on the Invention and Evolution of the Midwifery Forceps. As professor of midwifery in the University of Edinburgh and as one having exercised much care to, and shown ingenuity in, the perfection of the axis traction forceps Dr. Simpson spoke as an authority upon the subject. Many of his former pupils joined in the thanks accorded to him at the close of the address, testifying to the interesting and clear manner in which the subject had been placed before them.

The Consultative Medical and Surgical Institution.

No doubt the memory of the formation of this movement and the criticisms connected with it are still fresh in the minds of many of the profession. The first report of the committee was presented at the annual meeting held on Oct. 29th. The institution, it was stated, was established to lessen the strain on hospital charity by providing on terms within, and under conditions suitable to, their pecuniary means and position medical and surgical aid to those who would otherwise seek it gratuitously, or be unduly taxed by paying the usual consultation fees. The committee state that during the 21 weeks which had elapsed since the opening of the consulting rooms in May 222 patients consulted the consulting physician, Dr. H. Ward Irvine, 148 being men and 74 women. The various occupations of the patients are given and the committee go on to say that they consider this result very satisfactory notwithstanding the organised hostility of certain members of the medical profession. They moreover consider that the need for such an institution was both real and widespread. They look forward sanguinely to increased results for the future. When we read further we read that the financial result can hardly be regarded with the same amount of satisfaction, for the income and expenditure account shows a deficiency of £343 13*s* 6*d*. on the working of the institution to date—that is, 21 weeks. The committee, however, believe that before long the debit balance will disappear and that the institution will become self-supporting.

Oct. 30th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Black Smoke.

A STEP forward on suitable lines is being taken by the Salford Corporation in dealing with the smoke nuisance. Everyone knows that manufacturers all over the country pose as martyrs in a good cause—i.e., their own—if any attempt is made to lessen the nuisance which so many of them are busily engaged in producing. But Mr. C. H. Tattersall, the medical officer of health, thinks that there is no necessity for any black smoke, and that the conditions which lead to its prevention are advantageous to the manufacturers. The Health Committee of the corporation have therefore instructed him to issue a circular warning manufacturers and advising them as regards the prevention of black smoke. Deficient boiler accommodation is one of the chief causes of its occurrence, and bad stoking is another In the former case the Health Committee recommend the use of mechanical appliances which they say are necessary, and state that "if the boiler accommodation is adequate the firemen and not the manufacturers will be prosecuted." The committee wish it to be clearly understood by the manufacturers that "they must either provide adequate boiler accommodation or be responsible for the emission of black smoke." It is stated that in an ordinary Lancashire boiler, 30 feet by seven and a half feet, with a proper draught, the amount of coal used ought not to exceed 20 tons per week where hand-firing obtains. Where this quantity is exceeded mechanical appliances are considered to be necessary It is also stated that sufficient boiler accommodation together with firing by competent men give the most satisfactory results. The committee will prosecute the firemen, and not their employers, should an offence take place where the boiler accommodation is sufficient. The medical officer of health will be glad to confer with owners or managers of works in the borough as to the abatement of the smoke nuisance. It is quite fair to make the firemen bear their share of responsibility, for in many cases the masters have been at their mercy as regards emission of smoke. These men have thought it less troublesome to throw a quantity of coal occasionally into the furnace and thus to cause black smoke than to feed the furnace more frequently with less at a time.

The Milk-supply of Manchester.

An interesting and important letter from Dr. H. Ashby on the Manchester milk-supply appeared in the *Manchester Guardian* of Oct. 24th. He says that milk contaminated in the cowshed, in the shop, or in the household, is largely responsible for the infantile diarrhœa and other wasting diseases which swell the high death-rate of infants under a year old in this and other cities, but that condensed or preserved milk is often contaminated in the household and is as likely to give rise to diarrhœa as so-called fresh milk. He does not, however, altogether advocate the use of sterilised milk. The sterilising process destroys the bacteria of the infectious diseases (such as tuberculosis) and the many micro-organisms which get into the milk from the cowsheds and dairies, but it injures the milk as to its nutrient qualities and sterilised milk is not to be compared as a food with clean and pure fresh milk. He is, therefore, in favour of preventing the contamination of milk with bacteria rather than their destruction after they have entered the milk. He cites the experience of the Walker-Gordon Company of New York and London, the Copenhagen Milk Supply Company, and the Manchester Pure Milk Supply Company to show that this can be done. "By the inspection and care of the cows, the most rigid precautions in the handling of the milk in the cowshed and dairy by maintaining the milk at a low temperature, and supplying it ...... in sealed bottles contaminations are avoided and a more wholesome and safer milk can be supplied to the infant than by any sterilising process." A supply of such fresh milk as this in bottles sold at a reasonable rate and, as he significantly adds, "a levelling up of the habits of some of our fellow-citizens," would rapidly lower the infantile mortality. Perhaps the next generation of mothers now being educated in our schools may know that pure milk is more desirable than dirty milk, and that bread-and-butter, potatoes, meat, tea, and gin, are not suitable articles of diet for children under 12 months old. Or is this too much to expect? In a report to be presented to the Lancashire County Council on Nov. 1st Mr. Edward Sergeant, medical officer of health for the county, enforces the necessity of a pure milk-supply, especially with reference to tuberculosis, and he states that 50 per cent. of the cows in the ordinary farmer's shippon suffer from tuberculosis, while "from 1 to 2 per cent. have tuberculous udders secreting milk capable of rendering actively infectious the milk from the healthy cows when mixed with it."

Proposed Hospital for Infectious Diseases.

On Oct. 12th a town's meeting was held to consider the proposal of the Manchester Corporation to erect a hospital for infectious diseases on Carrington Moss, when a vote adverse to the scheme was given. A poll of the ratepayers has been demanded and in the meantime letters are appearing in the local press advocating or opposing the project. Exception is taken in one of the weekly papers to the proposed provision of 240 beds as excessive. It is based on the fact that of late years the cases of small-pox in Manchester have been few, and then follows a fallacious argument as to the effect of improved general sanitation: "Every year the sanitary condition of the city is improving, thanks to Alderman Walton Smith and his colleagues, and the *chief causes of small pox*—filth, bad air, and crowded dwellings in slum districts in proximity to polluted streams—are in process of being removed." As if filth, bad air, and over-crowding would produce small-pox in the absence of the specific cause. Objection is also taken to the estimate of £60,000 as being much too low, and £100,000 is considered as nearer the sum that would be required. No doubt 240 beds for small-pox cases may be nearer the theoretical standard for the population of Manchester than a smaller number, yet if we bear in mind the rate of spread of small-pox when all possible means of isolation are adopted, as will be the case in Manchester, and the eager way in which even anti-vaccinationists—as long as the disease is at a distance—flock to the medical man on its approach, there is some force in the plea for a smaller permanent hospital. This is all the stronger when it is remembered how rapidly temporary accommodation can be provided when required, if the ground is available and the requisite administrative facilities are ready and sufficiently elastic. As regards the site, it will puzzle the ratepayers or any of their leaders to find a better one than that at Carrington Moss. The neighbourhood of Manchester is so thickly populated that within an equal distance from the centre of the city it is more than doubtful if a piece of land can be acquired, at any cost, presenting so many advantages and so few disadvantages. Carrington Moss already belongs to the corporation, it has very few houses on it, and it fulfils the requirements of the Local Government Board more completely than any other suggested site. Nor does the objection that it has been used as a place of deposit for excreta and refuse apply more strongly than to agricultural land generally. Dr. Dixon Mann went over it some months ago and found no ground for objection; "the air was free from odour and the ground showed no signs of offensive matter." My own experience entirely confirms this. When I last visited the Moss vegetation was luxuriant, the air was sweet, fresh, and bracing, and the whole sweep of about 1200 acres showed the wonderful change that can be effected by energetic and skilful farming which, by the way, has not been unprofitable. The objectors on this score should read Dr. Vivian Poore's experiments.

Christmas Beer in the Workhouse.

As the day approaches on which we commemorate the announcement of the message of peace and goodwill the various boards of guardians have a contention as to whether those under their care are or are not to have any Christmas beer. The house visiting committee of the Chorlton Board of Guardians at their meeting on Oct. 26th recommended that beer should be supplied as usual to the inmates of the Withington workhouse with their Christmas dinner. An amendment, proposed by one lady guardian and seconded by another, that the question should be referred back to the committee was rejected. At the meeting of the Prestwich Board of Guardians on Oct. 25th a long discussion was introduced by a lady guardian who moved that the practice of giving beer on Christmas Day should be discontinued. This was seconded but lost, so that the Prestwich inmates will have their beer if they wish. But they have the choice of beer or milk, and many are said to prefer the latter Reason and moral considerations, arising chiefly from alcoholic abuse and its consequences, point in one direction, while sentimental regard for old-time customs, when some form of alcohol was thought an absolute necessary of life and the essence of good cheer, points in the other and is generally followed.

Appointments.

Dr. Robert B. Wild has been elected an honorary physician to the Cancer Pavilion and Home in succession to the late Professor D. J. Leech —On Oct. 22nd at the meeting of the special-committee of the trustees of the Manchester Infirmary for the appointment of honorary surgeons, Mr. W. P. Montgomery, M.A. Oxon., B.S., M.B. Lond., F.R.C.S. Eng., was appointed honorary assistant surgeon to fill the vacancy caused by the appointment of Mr. W. Thorburn as full surgeon.

Oct. 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Opening of the Diamond Jubilee Pavilion of the Edinburgh Royal Infirmary by Princess Henry of Battenberg.

ON the afternoon of Oct. 26th the ceremony of opening the new pavilion of the Edinburgh Royal Infirmary was performed by H.R.H. Princess Henry of Battenberg. The Princess, who was the guest of the Duke and Duchess of Buccleuch at Dalkeith Palace, drove into Edinburgh by the Cameron Toll, the old Dalkeith-road, Preston-street, and Nicholson-street. After lunching with the Lord Provost in Charlotte square Her Royal Highness proceeded to the infirmary by way of Princes-street and the Mound, all traffic being stopped along the route. A large number of tickets of admission to the infirmary had been distributed, so that the corridors along which the Princess was to pass were lined by persons anxious to see Her Royal Highness, while in the middle ward of the new pavilion sitting accommodation had been provided for holders of special tickets. After performing the ceremony of opening the outer door of this ward with a gold key, the Princess, attended by the managers and senior members of the hospital staff, walked through the ward to the south end, where a small platform had been erected. The Rev. Dr. Archibald Scott then opened the proceedings with prayer, after which the Lord Provost made an appropriate speech referring to the history of the Edinburgh Royal Infirmary and the principles on which it was worked, as well as to the persons by whose generosity it had been made possible for the managers to erect the new pavilion. The Lord Provost subsequently presented the key to Her Royal Highness, who then declared the building open. Professor Rankine in a short speech proposed a hearty tribute of thanks to the Princess for her services in having opened the pavilion, after which Her Royal Highness left the ward. After spending a short time in the institution the Princess and party drove back to Dalkeith, where Her Royal Highness spent the night, leaving for the north early on the morning of Oct. 27th.

The Diamond Jubilee Pavilion is to be especially devoted to the treatment of gynæcological cases. About half of the cost of the pavilion will be defrayed from the Diamond Jubilee Fund raised by the citizens of Edinburgh in 1897. Nine-tenths of the fund, amounting to £19,178 7*s.* 11*d.*, were given to the treasurer of the Royal Infirmary for this purpose. The whole cost of the p [illegible] £40,000, the additional £20,000 [illegible] reserved for purposes of extens [illegible] ıds immediately to the west of the medical pavilions on ground purchased by the managers from the directors of the Edinburgh Royal Hospital for Sick Children. The style of architecture is similar to that of the previously existing pavilions. The new pavilion, however, is larger than these, and being built of red stone has quite a distinctive character. The building is five storeys high, containing a basement floor, three floors of wards, and attics. At the south end are octagonal turrets rising to the height of 95 feet. Between the turrets are open balconies, and on one of these balconies is a granite memorial stone with an inscription as follows:—"Dedicated to the glory of God and the healing of human suffering in commemoration of the sixtieth anniversary of the accession to the Throne of Her Most Gracious Majesty Queen Victoria: the thank-offering of many for great benefits bestowed upon the realm during her reign." At the north east angle of the pavilion there is a large square tower within which is the staircase which measures 20 feet by 30 feet, and in the upper part there are electric fans for the ventilation of the building. The basement floor contains the new bathing establishment. This contains a Turkish bath with three hot rooms graduated in temperature, a douche room, and vapour, needle, sulphur, electric, and other medicated baths. The cooling room measures 70 feet by 10 feet, and there is ample provision for dressing-rooms, lavatories, and attendants' rooms. All the rooms connected with the bathing department are tiled both as to the floor and the walls, while between this department and the wards above there is a strong double concrete floor with intermediate ventilated air space which is intended to prevent the heat from the baths penetrating to the wards above. The new pavilion is connected with the main buildings of the infirmary by a covered corridor on the ground floor and by an open gallery on the first floor. The pavilion is provided with three lifts—for patients, food, and coals respectively.

The ward on the ground floor is intended for a reserve medical ward, to be used when any other ward in the medical hospital is being cleaned. The wards on the first floor and second floor are for gynæcological cases and will be under the care respectively of Professor A. R. Simpson and Dr. J. Halliday Croom. On these floors, in addition to the main ward, are an operating room, two special wards of two beds each, a demonstration or lecture room, an out-patients' room, and a physicians' room, as well as the ward kitchen, bathroom, lavatories, an isolation ward with one bed, nurses' bedrooms and parlour, linen stores, &c. The operating rooms have been tiled throughout. The walls of the pavilions are not strapped and lathed, but the plaster is laid on a brick lining separated from the outer wall by an air space. The floors are of iron and concrete and the floor boards are nailed to a layer of asphalt laid on concrete. The attic floor contains 14 single rooms for 14 nurses and seven rooms for servants, besides ample lavatory, bathroom, and boxroom accommodation. For heating the pavilion steam pipes and radiators will be used and in each ward there will be an open fireplace. The ventilation will be by means of electric fans placed in the tower in the north-east corner. Between this pavilion and the new laundry on the north there are being erected two buildings of smaller size—one for the treatment of diseases of the ear and throat, the other for diseases of the eye. The kitchen is also at present being much enlarged and improved at a cost of about £6000. Several storerooms have been taken into the old kitchen and the building has been doubled in height. It is tiled from floor to ceiling and is lined with new kitchen "plant" in the shape of boilers and ovens, from the size of which one feels assured that [illegible] the inmates of the infirmar [illegible]. It is 30 years ago since t [illegible] foundation-stone of the present buildings of the Edinburgh Royal Infirmary, and by this time not far short of half a million of money has been spent on the land, buildings, equipment, and enlargement of the institution which is now one of the largest hospitals in the country.

Dr. J. O. Affleck's Retirement from the Edinburgh Royal Infirmary.

A few weeks ago Dr. J. O. Affleck's term of office as an ordinary physician came to an end, the vacancy on the staff of the full physicians being filled by the promotion of Dr. G. A. Gibson to be a full physician. The managers of the infirmary at a meeting held recently adopted the following minute:—

Dr Muirhead, convener of the medical managers' committee, directed the attention of the board to the recent expiry of Dr J. O. [illegible]

[illegible] devotion he has ever bestowed upon the health and welfare of the patients as well as of the [illegible]

[illegible] infirmary.

Oct. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal University of Ireland.

THE meeting of Convocation of the Royal University of Ireland which was held in Dublin on Oct. 25th has, I regret to say, given rise to the utmost dissatisfaction to the great majority of graduates who were present. The principal business at the meeting was the election of a clerk of Convocation (at a salary of £100 per annum) and for this post there were five candidates: (1) Mr. W. H. Brown, M.A., LL.B.; (2) Mr. John Donaldson, M.A.; (3) Mr. Charles F. Doyle, M.A.; (4) Mr. James C. Meredith, M.A.; and (5) Mr. W. J. White, M.A. Lord Morris (Vice Chancellor) presided, and the small room in which the meeting was held was crowded with the supporters of the candidates who had come great distances to vote, as personal, not proxy, voting alone is allowed. The first point to be discussed was as to the mode of election, but most unfortunately a show of hands was allowed and this indicated very ea [illegible] following of the various candidate [illegible] Honour Judge Shaw, M.A., that [illegible] voting should be employed with [illegible] the choice of the majority pre [illegible] adopted. In other words, his advice was to put up all the candidates (each voter to record his vote for one) and after every time of voting to cut off the lowest on the poll until eventually the choice would lie between two. The Roman Catholic Bishop of Limerick urged that the proper plan was simply to take a show of hands and to declare the candidate with the largest number of votes elected. Serjeant Dodd, Q.C., suggested the method adopted by the Benchers of King's Inn, which would, in the end, practically give the majority of those present of tuberculosis to the extent that they are only notifiable when occurring in educational institutions, boarding schools, asylums, and hospitals, unless they are cases which terminate fatally, when they must be notified wherever they occur.

Oct. 29th.

NEW YORK.

(From our own Correspondent.)

The Massachusetts Arsenic Law.

The Massachusetts State Board of Health has secured an Act fixing severe penalties with regard to the use of arsenic in fabrics. The law as approved on May 18th becomes operative on Jan. 1st, 1901, and places the power in the hands of the State Board of Health. The Act provides that any corporation, firm, or agent, who directly or by an agent manufactures, sells, exchanges, or has in his custody or possession with intent to sell or exchange any woven fabric or paper containing arsenic in any form or any article of dress or of household use composed wholly or in part of such woven fabric or paper, shall on conviction thereof be punished by a fine of not less than $50 or more than $200; provided, however, that the section shall not apply to dress goods or articles of dress containing not more than $\frac{1}{100}$th of a grain, or to other articles or materials containing not more than $\frac{1}{10}$th of a grain of arsenic per square yard of the material. The State Board of Health shall make all necessary investigations as to the existence of arsenic in the material and articles mentioned in Section 1 of the Act and may employ inspectors and chemists for that purpose, and shall adopt such measures as they may deem necessary to carry out the provisions and to facilitate the enforcement of the Act.

Visual Defect and Railroad Service.

In order to ascertain what is being done in railroad circles in matters of this nature Professor Allport sent a letter of inquiry and a question blank to every railroad company in the United States, Canada, and Mexico, operating over 100 miles of road. 244 railroad companies were thus addressed, whose operations covered 205,386 miles of road. Professor Allport received replies from 64 companies whose operations extended over 90,950 miles of road, and he found that 53 of these exacted a systematic eye and ear examination of some kind. These examinations are undoubtedly not at all ideal in many instances, but they show that interest is taken in the matter. As to what men are subjected to such examinations the replies are differently couched, but it is evident that at least 50 of the companies require such examinations of all men directly engaged in moving and operating trains and in giving and receiving signals, such as engineers firemen, conductors, brakesmen, yardmen, signalmen, switchmen, &c. These examinations are made exclusively by the surgeons of the companies in 19 cases; 18 companies entrust the work to an employé, such as a division superintendent, train master, &c. Six companies send doubtful cases to an eye and ear surgeon; nine companies entrust the whole matter to a regularly employed eye and ear surgeon; and three companies first have the men examined by their surgeons who then send doubtful cases to the eye and ear surgeons. Three of these companies cause examinations to be made in all cases by surgeons of relief associations. One company has re-examinations every six months, four every year, 14 every two years, four every three years, and two every four years. Eight re examine whenever it seems advisable, as after severe illness or injury, or after a railway accident, or when certain incidents bring into question the reliability of the eyes or ears of an employé. One company requires re examinations only at times of promotion, and another when a man arrives at the age of 50 years. On 23 railroads it is claimed that perfect eyes and ears are required of new men, and that no concessions whatever are made to old employés On 16 of the railroads, while perfect sight and hearing are required of new men, various reasonable concessions are made to old employés. On one railroad the following requirements are made: engineers and firemen shall possess a vision of $\frac{20}{20}$ in one eye, and $\frac{20}{30}$ in the other. Conductors, flagmen, brakesmen, and switchmen must have a vision of $\frac{20}{30}$ in one eye and $\frac{20}{40}$ in the other; other employés must have a vision equalling $\frac{20}{40}$ in both eyes. On one railroad the applicant must possess eyes and ears the functions of which shall equal 75 per cent. of the normal function. One company requires perfect eyes and ears for firemen and all the employés to possess vision equalling $\frac{20}{20}$ in one eye and $\frac{20}{30}$ in the other. Another company sets the standard of vision at $\frac{20}{30}$ and declares that a whisper must be heard at a distance of 12 feet. One company requires a combined vision of $\frac{20}{20}$ and that neither eye shall drop below $\frac{20}{70}$, while another requires of engineers, firemen, signal-tower men, and switchmen vision of $\frac{20}{20}$ in one eye and $\frac{20}{30}$ in the other. Upon two railroads employés are retained who still possess vision equalling $\frac{20}{40}$ in both eyes and when the hearing is half lost in one ear, provided the other ear be perfect. Seven companies specifically state that old employés may wear distance glasses, if these will enable them to reach the proper standard; seven others especially state that they do not allow distance glasses during train duty when such glasses are necessary to bring vision up to the proper standard. It appears that on all points bearing upon the visual and aural capacity of railroad employés there is much diversity of opinion on the part of the employer and the employed and also on the part of railroad surgeons and eye and ear surgeons themselves. This is unfortunate, as it precludes the probability of meeting on mutual ground and formulating rules that shall be safe and yet not extreme or Quixotic.

Charitable Hospitals not Liable.

The United States Circuit Court lays down the rule that a beneficiary of a charitable corporation—as, for example, a patient in a hospital which is chartered or must be legally classed as a charitable institution—must take its bounty for what it is worth. It is inconsistent with the underlying idea of charities, as recognised by law, to hold that the same rule that applies to a person or an institution employed for compensation to do a certain service applies to the distribution of charity. The person who enters a charitable hospital is not a contractor; neither is the hospital a contractor with that person. The person who enters is a mere licensee, like a guest who enters a person's house and who must take the service as he finds it. He cannot have higher rights than members of the household of which he has for the time being become as it were a part. All he is entitled to is not to be led into a danger known to his host and not known or not reasonably apparent to himself. That, the court holds, is the precise rule that applies to a public charity, and in this respect it holds that private charity and public charity rest on exactly the same ground and there is no basis in either case to hold that the person who receives the bounty is a contractor, a person contracting for service as he engages service when he ordinarily employs a surgeon. He is in law only a licensee. Nor does the court consider that the reception—the frequent reception—of money from patients changes the nature of the institution; and the following out of this proposition, it says, necessarily leads to the conclusion that the reception of money from any particular patient does not change the nature of the service rendered to that patient, so far as anything said here is concerned. It looks at the money paid in such a case as a proper contribution to a charity on the part of the person who makes the payment and who receives the benefit of the charity. It is not compensation in the eye of the law. Furthermore, the court holds that the officers of a charitable institution have no power by contract to impose any liability beyond that which the law raises. If it is unsuitably or carelessly managed the remedy is in the hands of the State. So, for the reasons adduced, it holds the hospital in the case in which the above judgment was delivered not liable for an injury alleged to have occurred to a patient through the neglect of a nurse even in the case of a "pay patient," it being in law a charitable corporation.

The Health of the Army.

From the report of Surgeon-General Sternberg it appears that during the calendar year 1899 there were 229,885 admissions to sick report recorded in a mean strength of 105,546 regulars and volunteers. This is equivalent to a rate of 2187 06 per 1000 of strength, as compared with 2146 18 per 1000 during the year 1898, and with 1237 24, the mean annual rate for the decade 1888-1897. The deaths in 1899 amounted to 1945, equal to a rate of 18 43 per 1000, as contrasted with 27·99 during the year 1898, and with 6 69, the mean of the preceding decade. The principal causes of death and the rates per 1000 men contributed by them were: gunshot wounds, 5·10; other injuries, 1·57;

diseases, 0 99; pneumonia, 0 94; and variola, 0 80. The troops serving in Cuba had the highest rate of admission—2949 74 per 1000, as against 3113 54 per 1000 in 1898, the result of exposures during the active service of the Santiago campaign. The lowest admission-rate during the last year, 1677·51 United States. 58 per 1000 me ne-half of this being respons 1000 of strength The highest death-rate in 1898 per 1000 was reported from Cuba; of this rate 67·94 deaths were caused by disease and 26 61 by injury, gunshot wounds being responsible for the deaths of 21·69 men per 1000 of strength. Surgeon-General Sternberg in his annual report gives authoritative data which controvert the statements made as to an alarming condition of health among the soldiers on nd excitements of or the large sick among the troops prevalent among medical officers that in time of peace, when only garrison duty would be performed, the sick-rate of the army in these islands would be no higher than it ordinarily is in the United States.

Pan-American Congress.

The third Pan-American Congress will be held in Havana, Cuba, on Dec. 26th, 27th, 28th, and 29th, 1900. The Executive Committee is constituted as follows:—President: Dr. Juan Santos Fernandez. Vice-President: Dr. Gustavo Lopez. Treasurer: Dr. Enrique Acosta. Secretary: Dr. Tomasso V. Coronalo. Members of Committee: Dr. Vincente B Valdes, Dr. Jose J. Torralbas, and Dr. Eduardo F. Pla. The official languages of the Congress will be English, French, Spanish, and Portuguese. The sections will be as follows: (1) General Medicine; (2) General Surgery; (3) Military Medicine and Surgery; (4) Obstetrics; (5) Gynæcology and Abdominal Surgery; (6) Therapeutics; (7) Anatomy; (8) Physiology; (9) Pediatrics; (10) Pathology; (11) Ophthalmology; (12) Laryngology and Rhinology; (13) Otology; (14) Dermatology and Syphilography; (15 and 16) General Hygiene and Quarantine; (17) Orthopædic Surgery; (18) Mental and Nervous Diseases; (19) Mental and Buccal Surgery; (20) Medical Pedagogy; (21) Medical Jurisprudence; and (22) Railway Surgery.

Oct. 18th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Athens:* Dr. Alivisatos has been appointed Assistant Professor of External Pathology.—*Berlin:* Dr Moritz Litten has been appointed Extraordinary Professor of Internal Medicine.—*Bologna:* Dr. B. Nigrisoli has been recognised as *privat-docent* of Surgery.—*Breslau:* Dr Alfred Schaper has been appointed Extraordinary Professor of Anatomy in succession to the late Professor Born He was formerly Professor of Microscopical Anatomy and Embryology in Harvard University. He is to have charge of the Embryological Department of the Anatomical Institute. Dr. Thiemich has been recognised as *privat-docent* of Children's Diseases.—*Brussels:* Dr. de Boeck has been appointed Extraordinary Professor of Psychiatry.—*Budapest:* Dr. von Korányi has been appointed Extraordinary Professor of Internal Medicine and Dr E von Grósz Extraordinary Professor of Ophthalmology — *Buffalo, U.S A.:* Dr. Frederick Bush has been appointed to the chair of Physiology in succession to Dr. Pohlman.—*Christiania:* Dr. Harbitz has been appointed to the chair of Physiology.—*Copenhagen:* Dr. Bock has been appointed to the chair of Pharmacology —*Florence:* Dr. Angelo Nannotti of Sienna has been recognised as *privat docent* of Surgical Pathology.—*Freiburg (Baden):* Dr Autenrieth has been appointed Extraordinary Professor of Medical Chemistry.—*Freiburg (Switzerland):* Dr. Charles Dhéré has been appointed Professor of Physiology —*Gottingen:* Dr. Meissner, Director of the Physiological Institute, has intimated his intention of retiring at the end of the current session. The and Dr. Rudolph Beneke, *privat-docenten* of Pathological Anatomy.—*Halle:* Dr. Paul Eisler has been appointed Extraordinary Professor of Anatomy and Dr. von Herff Extraordinary Professor of Mi

Albrecht Kossel

Moscow has been appointed to the chair of Surgical Pathology.—*Naples:* Dr. C Addario of Catania has been recognised as *privat-docent* of Ophthalmology.—*Parma:* Dr. Vittorio Mibelli, Extraordinary Professor of Dermatology, has been appointed Ordinary Professor.—*Pisa:* Dr. Cesare Paderi has been recognised as *privat-docent* of Materia Medica and Pharmacology.—*Prague (German University):* Dr. Friedrich Weleminsky has been recognised as *privat docent* of Hygiene.—*Rio de Janeiro:* Dr. A. Bittencoust has been appointed Professor of Medical Physics and Organic Chemistry.—*Vienna:* Dr. Julius von Hochenegg has been entrusted with the duties of the late Professor Albert's chair of Surgery until a new appointment can be made; Dr. Jakob Pal has been appointed Extraordinary Professor of Internal Medicine; Dr. Emil Redlich, Extraordinary Professor of Neurology; Dr. Salomon Ehrmann Extraordinary Professor of Dermatology; and Dr. A. Elsching and Dr. L. Königstein Extraordinary Professors of Ophthalmology.

VACCINATION IN GLOUCESTER.—At the meeting of the Gloucester Board of Guardians held on Oct. 23rd it was decided to forward to the Local Government Board full particulars respecting the continued neglect of the vaccination officers to carry out the order of the Local Government Board. It was stated that in 1898 out of 1600 births there were between 200 and 300 vaccinations, and in 1899 there were 700 vaccinations, but since then, owing to the loose manner in which the Act was administered, the number had greatly diminished.

VIBRONA ART SERIES.—We have received copies of Nos. 5 and 6 of this series. The pictures selected for reproduction are Rosa Bonheur's "Horse Fair" and Constable's "Hay Wain," both of which magnificent works hang in the National Gallery. The reproductions are issued at the nominal price of 2*s.* 6*d.*, and, as we have already observed when referring to two previous pictures of the series in our issue of May 26th, are free from any advertisement. Messrs. Fletcher, Fletcher, and Co. in giving the public a chance of securing these really artistic reproductions in sepia of some of the finest national pictures are doing a practical service to art.

UNIVERSITY OF CAMBRIDGE.—The Vice-Chancellor announces that he has received from Mr. W. W. Astor the munificent donation of £10,000 for the University Benefaction Fund. This will greatly aid in the erection of the building for botany and for pathology and medicine, the plans of which have already been approved by the Senate Dr. Haddon, F R.S., has been appointed university lecturer in ethnology and Mr. J. J. Lister, F.R.S., university demonstrator in comparative anatomy. A university lectureship in physics is vacant by the resignation of Professor Wilberforce, now of Liverpool. The Mater Misericordiæ Hospital, Dublin, has been recognised by the Special Board for Medicine as a place of clinical study. At the congregation on Oct. 25th Mr. A. C. Rendle, B.A., Christ's, was admitted to the degree of M.D.; and Mr. E. Talbot, M.A. Trinity, and Mr. G. H. Hunt, M A. Clare, were admitted to the degrees of M.B. and B.C.

THE LOCAL GOVERNMENT BOARD AND THE SMOKE OF BRENTFORD.—The Brentford District Council lately received a communication from the Local Government Board inclosing a report from the Coal Smoke Abatement Society. The report of the society contained particulars of the times during which nuisance had been caused by the Waterworks Company. A member of the Brentford District Council gave it as his opinion that this matter had already received sufficient attention at their hands as they had already received a report from their own inspector and had already stated that they were exercising a constant supervision. The clerk to the council suggested that the council should assume a firm attitude. They should state that the town was essentially a manufacturing town and that they were not disposed to enforce the Act strictly. "The Local Government Board," he suggested, "might do what they liked." We can hardly suppose that the Local Government Board will be intimidated by the clerk of the Brentford District Council. Time will show.

Bristol Municipal Elections.—Mr. Colston Wintle, L.R.C.P. Lond., M.R.C.S. Eng., has been returned unopposed for the Horfield Ward of the Bristol Town Council.

The Sanitary Inspectors' Examination Board.—The next examination for certificates of qualification for appointment of sanitary inspector or inspector of nuisances, under Section 108 (2) (d) of the Public Health (London) Act, 1891, will be held in London on Tuesday, Jan. 15th, 1901, and the four following days. Particulars will be forwarded on application to the honorary secretary, Mr. W. R. E. Coles, 1, Adelaide-buildings, London Bridge, E.C.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Tomashevski, who was for 40 years director of the Nicholas Children's Hospital in St. Petersburg.—Dr. William Webb Browning, Professor of Anatomy in Long Island College Hospital, Brooklyn.—Dr. Maximino Teijeiro, Professor of Clinical Surgery in the University of Santiago, Spain.—Dr. H. H. McGuire, former Professor of Surgery in Richmond, U.S.A.—Dr. A. Stillé formerly Professor of Medicine in the University of Pennsylvania.

Free Home for the Dying.—The dedication of the new and permanent building for the Free Home for the Dying, 29, North-side, Clapham-common, took place on Oct. 26th. The building, which was formerly the residence of the late Sir Charles Barry, has been transformed by Mr A. E. Street, who has himself made a donation of £100 towards the building fund. The purchase of the freehold and the cost of the alterations and repairs have involved an outlay of more than £10,000, and of this amount a sum of £3000 has still to be collected. It is hoped that the public will shortly relieve the institution of this debt. The Bishop of Southwark, who performed the dedication ceremony, in the course of his address stated that a munificent donation of £1000 had been given that day to endow permanently one of the beds. The building is well adapted for its purpose; it contains 25 beds, of which 12 are in the women's ward, eight in the men's ward, and the remainder in separate rooms.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Anderson, J., M.B., C.M. Glasg., has been appointed District Medical Officer for the No. 5 Sanitary District, Sunderland Union.

Bathe, Allan Arthur, M.A., M.B. Oxon., has been appointed an Honorary Medical Referee by the Board of the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, Isle of Wight.

Brown, H. C., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Dudley Union, vice J. Brown, deceased.

Buick, James, M.B., Ch.M. Glasg., has been appointed Certifying Medical Officer for the purposes of the Factories and Shops Acts, Melbourne, Australia.

Corbet, L. F., L.R.C.P., L.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Killoughey Dispensary District in the Union of Tullamore.

Gillies, Sinclair, M.D. Lond., L.R.C.P., M.R.C.S., D.P.H. Camb., has been appointed Official Visitor to the Hospital for the Insane, Parramatta, and the Licensed House for the Insane at Cook's River, Sydney, New South Wales.

Grannum, W. B., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, Luton Union, vice D. R. McArthur, resigned.

Haworth, James, M.B., Ch.B., has been appointed House Surgeon to the Sunderland Infirmary.

Hill, Alfred W., M.D. Brux., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Specialist to the Ear and Throat Department of the Adelaide Hospital, South Australia.

Hobbs, Geoffrey C., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Hampstead Hospital, N.W.

Huey, J. J., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Mexborough Sanitary District.

Hunt, J. S., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Superintendent to the Dunwich Benevolent Asylum and Medical Officer for the Care, Supervision, and Inspection of Lepers at Stradbroke Island, Queensland.

Jaques, A. S., L.R.C.P. Lond., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, Gateshead Union, vice A. Green, resigned.

Kennedy, R. C. H., B.A., M.B., B.Ch. Dub., has been appointed House Surgeon to the Royal Isle of Wight County Hospital, Ryde.

Kyle, H. G., B.A., M.B., B.Ch. Oxon., has been appointed House Surgeon to the General Hospital, Bristol.

MacDougall, R., L.K.Q.C.P. Irel., L.R.C.S. Irel., has been appointed Public Vaccinator for Rokewood, Victoria, Australia.

McKee, F. C., B.A., M.B., B.Ch., B.A.O. R.U.I., has been appointed House Physician to the Sunderland Infirmary.

McSweeny, M. S., M.B., Ch.B. Melb., has been appointed Public Vaccinator for Milawa, Victoria, Australia.

Merryweather, S. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, Horncastle Union, vice W. P. Simpson, resigned.

Neill, Channing, M.B., Ch.M. Irel., L.R.C.S. Edin., has been appointed Medical Officer at Eidsvold, Queensland.

Pitts-Tucker, F. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator to the Sutton Sanitary District, Ely Union.

Platt, J. E., M.S. Lond., F.R.C.S., has been appointed Assistant to the Professor of Surgery in the Owens College, Manchester.

Scott, H. J. H., L.R.C.P. Lond., M.R.C.S., has been appointed a Member of the Licensing Court for the District of Scone, New South Wales.

Thorowgood, John C., M.D. Lond., F.R.C.P., has been appointed Consulting Physician to the Royal National Hospital for Consumption at Ventnor, Isle of Wight.

Todd, D. B., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Westbury and Whorwellsdown Union, vice G. G. Parsons, resigned.

Wassell, Jas. L., M.B., M.Ch. Syd., has been appointed Medical and Health Officer at Thursday Island, Visiting Surgeon to the Prison at that place, and Medical Officer for the Care, Inspection, and Supervision of Lepers detained in the Lazaret at Friday Island, Queensland.

Willson, Rivers, Ph.D., L.S.A. Lond., has been appointed Surgeon to the Oxford Medical Dispensary and Lying-in Charity, vice Chas. Ballard, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bagthorpe Isolation Hospital, Nottingham.—Resident Medical Officer for twelve months. Salary £100 per annum, with board and residence. Apply to the Medical Officer of Health, Guildhall, Nottingham.

Birkenhead and Wirral Children's Hospital, Woodchurch-road, Birkenhead.—House Surgeon for twelve months. Salary £100 per annum, with board, residence, and laundry.

Birmingham and Midland Hospital for Skin and Urinary Diseases, John Bright street, Birmingham.—Clinical Assistant.

British Hospital, Oporto, Portugal.—Medical Officer. Salary £15 per annum, with liberty to engage in private practice. Apply to the Treasurer, Mr. R. Coverley, 55, Rua da Reboleira, Oporto.

Cardiff Infirmary.—Assistant House Surgeon for six months. Salary at the rate of £75 per annum, with board, washing, and apartments.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150 by £10 annually, with board, furnished apartments, &c.

Dundee Royal Lunatic Asylum.—Medical Assistant.

French Hospital and Dispensary, 172, Shaftesbury-avenue, London.—Resident Medical Officer (not a female), speaking French, and unmarried. Salary £80 a year, with full board.

N B —A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CHESTER HOSPITAL SCANDAL.

A GREAT to-do has been made at an inquest recently held at the Chester Infirmary concerning the death of a man named John Williams. He was admitted to the infirmary on Oct. 1st with an impacted fracture of the neck of the femur. He remained in the infirmary until Oct 12th when he was removed to the workhouse where he died. The reason for his removal was that he was very noisy and dirty in his habits and disturbed the other patients He could not be put into a ward by himself, as the Chester Infirmary has no separate accommodation for such cases. This narrative of events has been made the text for diatribes by the Chester coroner and by the *Manchester Evening Chronicle* of Oct 23rd The coroner is reported to have said that "If the man had been *in a good position of life he would not have been sent to the* workhouse It was, in his opinion simply due to the fact that he was a poor man and unable to pay for his board and lodgings at the infirmary that he was sent to the workhouse" The *Manchester Evening Chronicle* adds: "Surely further comment is superfluous" We do not think so The same journal talks about the callous way in which the aged poor are handled in our hospitals This charge, as anyone knows who is conversant with hospitals, is absolutely unfounded As to the coroner's remarks (if they are correctly reported) they are foolish If Williams had been well to-do he would have been treated neither at the infirmary nor at the workhouse but at his own home by his own medical man Every medical man knows that an impacted fracture of the neck of the femur in an old person (and Williams was over 70 years of age) should not be treated by keeping the limb rigid or the patient lying down The house surgeon of the infirmary informs us that Williams was removed in a cab to the workhouse comfortably wrapped up, lying on pillows and a fracture-board He was admitted to the workhouse on Oct 12th and died on Oct 19th In our opinion the authorities of the infirmary did the best in their power both for Williams and for the other patients by removing him to the workhouse

A QUESTION OF ETIQUETTE

To the Editors of THE LANCET

SIRS,—I shall feel greatly obliged if you will kindly give me your opinion as to the conduct of B in the following case A, on receiving a message from people he had previously attended, visited the house and found a boy with symptoms of scarlet fever There was no rash but he had been ill only a few hours. The following day A was unable to see the boy, who lived two miles away B was passing through the village and was called in After examining the boy B was informed that A was attending, but in spite of this B notified the case as scarlet fever The next day A made a special journey, and on arriving at the house was told that the boy had been removed that morning to the isolation hospital A wrote to B for an explanation and received the following reply "I much regret that the case of —— should have caused you any annoyance, but as I was called in to see the boy and the mother was anxious to have him removed as soon as possible I felt myself bound under the Act to notify the case and to ask the inspector to remove him without delay The mother of the child did not tell me you were in attendance till after I had examined him"

I am, Sirs, yours faithfully,

Oct 29th 1900 MEDICUS

*** B was asked for an opinion upon the case and gave it. He was not [illegible] till after he had [illegible] we cannot see how anything of an unpleasant nature can arise in the matter between two gentlemen of the same profession —ED L.

"MOTOR CARS FOR MEDICAL MEN"

To the Editors of THE LANCET

SIRS,—Your correspondent Mr Claude A. P Truman (*vide* THE LANCET, Oct. 20th, p. 1176 wisely refrains from giving his experience of motors *since* beginning with his "trike", besides I do not consider a "trike" worthy of discussion as of use to a medical man by reason of its unsuitability and discomfort in wet or cold weather. If I have given myself away I am quite willing to restore myself to my own bosom by saying that I *do* deplore the condition of humanity as evidenced by full hospitals as I do full motor hospitals, but the two subjects are scarcely comparable the one being an ancient and unavoidable evil, the other a modern question of practical utility If the population of this country were reduced to 1000 and 800 were in hospital I should say that life would be scarcely worth living Mr Truman admits that cars *do* break down, and compares them with the vagaries of horses, but taking into consideration the enormous number of horses used for all purposes I maintain that the number of breakdowns due to them bears but a microscopic proportion to those due to motor cars. I kept for nearly 30 years two horses and can honestly say that my accidents were infinitesimal. It is because perfection in motors is still so far off that I advised medical men to ponder—that is, if they want a machine for *honest work* If they want it only for pleasure and possess a deep pocket, then by all means let them try any number of cars and shout when they succeed. Your correspondent "Motist" speaks the truth in saying "what a medical man wants in a motor is one that can be as easily controlled and managed in going from house to house as an ordinary horse and trap and not one made for speed." When this is on the market the utopian stage will set in. "Benz Car" seems to have been more fortunate in his experience, but it would be interesting to know how often his worries with tyres, chains, and wheels occurred, and what the "&c." implied? It also appears to me a pretty large order for the upkeep of one small car, between £30 and £40 annually. After all the question is one of cost and efficiency and I repeat my opinion that the motor up to the present time does not fulfil the requirements of a medical man for all-round work.

I am, Sirs, yours faithfully,

Oct. 22nd, 1900. MOTOR-CAR.

WANTED—A HOME.

DR. HERBERT HART, 101, Queen Victoria-street, E.C., is anxious to know of a comfortable home or an institution for a girl of weak intellect. Her father is willing to contribute 7*s.* 6*d.* per week towards her maintenance. She is 15 years of age and when young she suffered from hydrocephalus. She has always been a dull child and although not exactly an imbecile requires to be under careful management.

THE DANGERS OF STRYCHNINE.

To the Editors of THE LANCET.

SIRS,—A young man, aged 27 years, was suffering from cardiac dropsy. He had, *inter alia*, considerable ascites, which had been tapped the day previous to Sept. 6th. On the morning of the 6th I gave him a hypodermic injection of strychnine, dissolving a tablet of one sixtieth of a grain of sulphate of strychnine. My patient derived a great deal of benefit from the hypodermic injection. On the following morning at exactly the same time (10 A.M.) I repeated the injection. Half an hour afterwards I was sent for. I went immediately to find my patient in undoubted convulsions from strychnine poisoning. The muscles of the back and arms were chiefly involved. The terror-struck face, the prominent eyeballs, the dilated pupils, and cyanotic complexion formed a picture I shall not readily forget. I at once administered 10 grains each of bromide of potassium and chloral hydrate, with the result that the convulsions wore away into twitchings and finally ceased within an hour. The patient died seven hours afterwards, but, as far as one could tell, solely from his cardiac condition, for his death had been expected daily. Call it idiosyncrasy or what you will, I shall hesitate to use strychnine again in a similar case. The only medicine the patient was taking was five minims of tincture of digitalis every four hours in a teaspoonful of water.

I am, Sirs, yours faithfully,

Oct. 30th, 1900. M.R.C.S.

P.S.—The wholesale chemists from whom the tablets were obtained have examined the tablets remaining in the tube and find the quantity of strychnine contained in each correct.

HOSPITAL ABUSE: A SIDE THAT IS SOMETIMES OVERLOOKED.

To the Editors of THE LANCET.

SIRS,—One cannot be a regular reader of your correspondence columns without seeing numerous complaints from the general practitioner about hard times and the ready explanation of this by the competition of general and special hospitals. Who is to blame for this? If the practitioner sends to hospitals every case from a tied tongue to a whitlow that cannot be met with the usual bottle of medicine he can scarcely grumble at other and more remunerative cases going to hospitals on their own initiative. I have recently had under my care at a hospital two instructive cases. One was a case requiring an abdominal section in a patient, sent in by her medical attendant, who told the matron very innocently that she had not wished to pay for her operation because she had just purchased an 80-guinea piano and desired to avoid more expense. Her daughter obtained reduced terms from another special practitioner because of the expense her mother's operation had entailed on the family. The second case was a urethral caruncle in a woman who lived in a superior street. In accordance with our rule a circular was sent to her last medical attendant stating that she had applied for treatment and inviting him to say whether the patient was a fit person to receive charity. This gentleman replied that he saw no reason to doubt her suitability. When the woman was dismissed from hospital her friends offered to pay any sum if we would retain her till it suited her convenience to return home. Such cases are constantly arising. Others occur where a practitioner sends patients into hospital and receives fees of five guineas and upwards, as we subsequently learn, for being present ("assisting") at the operation. Most hospital surgeons could furnish many similar instances of hospital abuse encouraged or instigated by general practitioners. I gladly acknowledge that it is the exception, but while such things occur it scarcely lies with the general practitioner to rail at hospitals for depriving him of a livelihood. I have yet to meet with the surgeon, hospital or otherwise, who is anxious to work for nothing or who would not be glad to receive patients before they have been drained of their fee-paying capacity by a long course of useless medical treatment. Let us be fair and face the facts. I submit that hospital abuse is as much caused by the general practitioner as by either the consultant or the public, and that, though it is heresy to say so, the hospital surgeon has as much right to a living as the general practitioner and as much right to the rewards of his work and reputation. Neither is he called upon to ask that gentleman's permission to exist at all, nor to do so on anything but the refuse of his practice or generous doles of patients of whom he is weary or who are weary of him.

I am, Sirs, yours faithfully,

Oct. 28th, 1900. A HOSPITAL SURGEON.

"CHRONIC INERTIA."

IN the Local Government Board report just issued Mr. Preston Thomas relates an amusing instance of laziness and vagrancy. A sturdy loafer repeatedly applied for relief on the ground of his inability to work, but he had not been able to induce a medical man to support his plea. He came, however, triumphantly at last with a medical certificate which testified to his being affected with "chronic inertia." He was surprised, not to say disappointed, that his application was again refused.

THE FEET OF CHINESE WOMEN.

DR. R. SMYTH of Ningpo writes as follows in *Mercy and Truth* with regard to the Chinese practice of foot-binding:—

> "It is a remarkable fact that over 90 per cent. of the leg compound fractures we meet with occur in women. This must be attributed to the almost universal practice of foot-binding. The little Chinese girl's feet are perfectly natural in shape and size until the time of binding—usually the seventh year. Distortion then begins. A long bandage of cotton cloth, a few inches wide, is firmly applied in figure-of-eight form, and the tightness of the bandage is increased at intervals until the desired size is attained. The resulting distortion is as follows:—The tarsus or instep is bent upon itself, the heel bone is thrown out of the horizontal, its previously posterior surface becoming inferior, and the four smaller toes are pressed down under the sole, until, finally crushed and attenuated, they lie folded under the great toe. The process of footbinding—never a painless one as the native proverb testifies, 'For every pair of bound feet there is a rain-tubful of tears'—is excessively painful when the professional bandager does her work badly. In such cases caries, necrosis, or deep ulcer may follow, especially when the little victim inherits a strumous constitution. If, on the other hand, the binding is done evenly and well, pain soon subsides, and sensation in the foot becomes partially or wholly lost."

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND LONDON, ENGLAND

During the week marked copies of the following newspapers have been received: *South Wales News, Evening Times (Glasgow), Science Siftings (London), Alliance News, Birmingham Daily Post, West Morning News, Daily Mail (London), Daily Express (London), Liverpool Daily Post, Blackburn Daily Telegraph, Bristol Times, Leicester Daily Post, Western Mail (Cardiff), Dublin Daily Express, Nottingham Daily Journal, East Anglian Daily Times, Redditch Indicator, Leeds Mercury, Oxford Chronicle, Sheffield Daily Telegraph, Dundee Advertiser, Manchester Guardian, Times of India, Pioneer Mail, Citizen, Scotsman, Rural World, Cambrian Times, Builder, Architect, Bristol Mercury, Mining Journal, City Press, Yorkshire Post, Local Government Journal, Reading Mercury, Surrey Advertiser, Hertfordshire Mercury, Australasian Medical Gazette, Sanitary Record, Chatham News, Brisbane Courier, Rangoon Times,* [illegible] *Examiner, Windsor Chronicle, Enfield Observer, Church Family Newspaper, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Dr. J. Adam, West Malling; Dr. J. H. Aston, Guatemala City; Mr. W. H. Arsell, Messingham; Messrs. Arnold and Sons, Lond.; Dr. H. de M. Alexander, Perth; Dr. Frank Arnold, Geelong, Rhodesia; Association for Pure Vaccine Lymph, Lond., Secretary of.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents

Agent for the Advertisement Department in France.—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Bradshaw Lecture

ON

THE URINARY PIGMENTS IN THEIR PATHOLOGICAL ASPECTS

Delivered before the Royal College of Physicians of London on Nov 6th, 1900,

By ARCHIBALD E GARROD, M D Oxon, F.R C P Lond,

PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND STREET MEDICAL REGISTRAR AND DEMONSTRATOR OF MORBID ANATOMY AT ST BARTHOLOMEW'S HOSPITAL.

MR PRESIDENT AND GENTLEMEN,—The invitation to deliver a lecture before such an audience as this at the same time confers a great honour and imposes a heavy responsibility For the honour I beg to offer my sincere thanks, and to the distinguished men who have preceded me in the position which I for the moment occupy I desire to apologise in advance for any failure on my part to attain to the high standard which they have set up

THE CLASSIFICATION OF URINARY PIGMENTS

The grouping together, under the collective name of "urinary pigments," of a number of substances which need have nothing in common beyond the facts that they are met with in the urine and are possessed of colour, can only be looked upon as a temporary expedient, although it may be justified on grounds of convenience, and is even rendered necessary by the incompleteness of our knowledge It may confidently be predicted that in the course of time this will share the common fate of such elementary classifications and that the group will undergo a gradual disintegration, as one by one its individual members can be referred to their true places in the chemical scheme Some of the substances usually included do not even fulfil the above two conditions, but are merely coloured products formed by the action of reagents upon constituents of urine which are themselves colourless Among these are urorosein and the indigo pigments, although of these latter indigo blue is occasionally met with as a sediment or in impalpable suspension in urine in which it has been formed by the decomposition of indoxyl glycuronic acid, the less stable of its parent substances

Even of the urinary pigments more correctly so called not a few are excreted, either wholly or in part, as colourless or faintly coloured parent substances, which quickly become converted into their coloured derivatives when the urine is exposed to light and air These very unstable precursors are known as "chromogens" a convenient term which makes no assumption as to their true nature When once the chromogen has been isolated and sufficiently studied we no longer speak of it as such Thus it is not customary to describe indoxyl sulphuric acid as the chromogen of indigo blue and red, or homogentisic acid as the chromogen of the alkapton pigment

Coloured substances may enter the alimentary canal in articles of food, in sweetmeats or in medicines, and may be thence absorbed and excreted either altered or unaltered by the kidneys With these may be included pigments formed during the passage through the body of constituents of food or drugs which are not themselves coloured, such as the oxidation products of the dioxybenzenes present in carboluria, and the yellow santonin pigment It is important that one should have [illegible] in order that one [illegible] in themselves they [illegible]

In yet a third [illegible] nts which are normal constituents of [illegible] body, but [illegible] only find their way into the urine under morbid conditions Such are hæmoglobin, bilirubin, biliverdin, and melanin, which last may appear in abundance in the urine, mainly as a chromogen, in cases of disseminated melanotic sarcoma The excretion of such pigments by the kidneys affords diagnostic indications of great value, but these indications are, for the most part, well recognised, and their interpretation forms part of the daily routine of clinical practice

special cause, seeing that they may all be present, if only in traces, in the urine of persons who may fairly be considered to be in normal health I refer to urochrome, urobilin, hæmatoporphyrin, and uroerythrin, and it is to the consideration of these four pigments that I propose to devote the time at my disposal this afternoon Urochrome is the most abundant of the urinary pigments, and to it the familiar yellow colour of normal urine is probably entirely due Urobilin, which only occurs in very small amount in normal urine and wholly in the form of chromogen, has no influence upon its colour, but in many morbid conditions it appears in greatly increased quantity and to a large extent as the formed pigment Under such circumstances it has a distinct effect upon the colour of the liquid and its single dark absorption band is conspicuously visible on direct spectroscopic examination without the addition of any reagent Hæmatoporphyrin is present in mere traces in normal urine and often in increased quantity in disease, but only very seldom does it occur in sufficient abundance to have any material effect upon the colour Uroerythrin, if not strictly a normal urinary constituent, may appear in small amounts as the result of very trifling deviations from perfect health In morbid urines it is often abundantly present, and it is chiefly conspicuous as the colouring matter of pink urate sediments

UROBILIN

Since its discovery by Jaffe,[1] in 1868, urobilin has attracted far more attention than the other members of the group, and there has grown up around it a literature which far exceeds in bulk that of all the other urinary pigments put together On this account it will be more convenient to consider it first The interest which it has awakened has been largely due to Maly's[2] observation that by the action of sodium amalgam upon bilirubin a product is obtained which in its main properties resembles urobilin very closely, so closely, indeed, that the identity of the two has been widely assumed, and the name of hydrobilirubin is not infrequently applied to the urobilin of urine, as also to the stercobilin obtained from fæces by Vanlair and Masius[3] However, there have always been some who have questioned the identity, although not the similarity, of urobilin and Maly's hydrobilirubin, which differ not a little in their minor properties and some combustion analyses of urobilin carried out by Mr F G Hopkins and myself[4] show that whereas the urobilin of urine and the stercobilin of fæces are identical in composition as also in properties they differ conspicuously from hydrobilirubin, especially in the much smaller percentage of nitrogen which they contain

—	Hydrobilirubin (Maly)	Urobilin (Hopkins and Garrod)
C	64·68	[illegible]
H	6·93	[illegible]
N	9·22	4·11
O	19·17	[illegible]·47
—	100·00	100·00

It would seem, indeed, that there is a group of substances which agree in showing the absorption band of urobilin and in exhibiting a brilliant green fluorescence with zinc chloride and ammonia but which differ in stability and other minor respects and are not chemically identical Such urobilinoid products have been obtained from bilirubin hæmatin hæmatoporphyrin and urochrome by the action of reducing agents and from some of these by what appear to be processes of oxidation That they have something in common seems evident and we are surely justified in regarding them as affording important evidence of the chemical relationship of the substances from which they are obtained

Of the chromogen of urobilin we know very little as yet, increased excretion in the urine is connected with increased production in the intestine, as evidenced by the presence of unusual quantities in the fæces.

The effect of constipation upon the excretion of indican, the parent substance of which, indol, is formed by bacterial action in the intestine, is so marked that it is natural to expect that it will have a similar effect upon the excretion of urobilin in urine, the stagnation of the contents of the colon allowing more time for absorption. George Hoppe-Seyler states that retention of the contents of the colon does increase the urobilin of urine, but that obstruction of the small intestine has no such effect. Dietrich Gerhardt, on the other hand, attaches little importance to constipation in this connexion and quotes cases of perityphlitis treated by opium in which when the temperature fell there was an enormous decrease of the urinary urobilin, although the intestines were still kept at rest. He also gives a series of observations upon a convalescent patient whose bowels were only moved every fourth or fifth day. Here, it is true, the maximum of urobilin in the urine was reached on the day following an action of the bowels, but if we admit (as I think we must, from what is seen when occlusion of the common bile duct occurs) that the absorbed urobilin is only slowly excreted, his figures point to a distinct increase of excretion under the influence of constipation, the full effect of the evacuation being seen only on the third day after its occurrence. Bargellini,[26] who made an elaborate series of observations bearing upon this point, arrived at the conclusion that in simple atony of the bowel the degree of constipation is without influence upon the amount of urinary urobilin, but that in cases of typhoid fever it causes an obvious increase, whereas disinfection or emptying of the lower bowel caused a noticeable decrease in the amount. If we study Bargellini's tables we find that a similar explanation may be given of many of his results. In several typhoid fever cases a continuous series of daily observations were made, whereas in none of the other cases were observations carried on to the second and third day after the evacuation of the bowel. Further observations upon this point, bearing in mind the slowness of the excretion of the absorbed urobilin, would be of much interest.

The most serious objection which has been raised to the intestinal theory is based upon the connexion which undoubtedly exists between urobilinuria and liver diseases. It is by no means the case that marked excess of urinary urobilin is always associated with obvious hepatic derangements, but there can be no question that conspicuous urobilinuria usually accompanies such diseases as cirrhosis and carcinoma hepatis. This fact, coupled with the presence of urobilin in the bile, formed the basis of the hepatic theory of Hayem and Tessier. However, the theory that the liver itself, and especially the disordered liver, manufactures urobilin, whilst it will explain the association under discussion entirely fails to explain the disappearance of this pigment from the bile and urine alike when the bile duct is occluded and its reappearance in both when bile is introduced into the stomach.

There are two different ways in which the influence of the liver may be reconciled with the intestinal origin of the urobilin of urine. We may suppose either that the condition of the liver exerts its influence at the beginning of the cycle by affecting the quantity and quality of the bile entering the intestine, and so indirectly the amount of urobilin formed, or that the liver lays hold upon the urobilin after its absorption and excretes it in part in the bile and in part converts it into some other substance. There can be little doubt that the state of the liver exerts an influence upon the *quantity* of bile-pigment formed and Riva and Vitali have shown that in phosphorus poisoning and acute yellow atrophy respectively the destruction of the liver cells practically puts an end to the formation of bile-pigment and that as a consequence urobilin may disappear from the fæces and urine. We should, indeed, expect that such quantitative influences would tell in the direction of diminution rather than increase. On the other hand, the hepato-intestinal theory of Riva,[27] which he has worked out with the aid of L. Zoja[28] and other members of the school of Parma, attributes to the condition of the liver an important influence upon the *quality* of the bile-pigment formed. The differences of quality are evidenced by the colour of the bile, of which the reddish-brown variety yields urobilin much more readily than the greenish. According to Zoja[29] the essential difference lies in the relative amounts of bilirubin and biliverdin present. These authors, together with Cavalli[30] and Chiodera,[31] have clearly shown that different biles exhibit marked differences in respect to the ease with which their contained pigment is converted into urobilin and that the bile of different animals differs widely in this respect, the green bile of vegetable feeders yielding urobilin less readily than that of carnivora. Cavalli also found that the bile obtained from the bodies of human patients agreed in its characters with what might be inferred from the excretion of urobilin during life. It is evident that this theory involves the formation from bile-pigment of other products besides urobilin, for if under normal conditions it is all converted into urobilin in the intestine increased convertibility can obviously lead to no increase of the yield. It also [illegible] of the quantity of urobilin i[illegible] intestine, unless, as Riva hi[illegible] pigment be not all excreted [illegible] is most probable, urobilin is [illegible] from the bile-pigment it seem[illegible] bile must have a material effect upon the quantity of urobilin produced in the intestine, and the question is rather whether the qualitative changes in the bile formed by disordered livers are so great as this theory demands—in a word, whether it is capable of explaining all the facts.

An alternative theory, origi[illegible] and independently by Beck, has [illegible] a pupil of the former. Vitali [illegible] cells have a strong affinity for urobilin, which they pick out from the blood, after it has been absorbed from the intestine, and re-convert into bilirubin. He further supposes that these cells have a still greater affinity for hæmoglobin and bilirubin, and that if they are called upon to deal with these latter pigments the urobilin brought to them may escape conversion. Thus when excessive hæmolysis is going on the liver cells may be so occupied that the urobilin passes them unchanged, or more urobilin may be brought to them than they are able to cope with, whereas disease of the liver may be supposed to lead to the same result by impairing the power of the cells to deal with the pigment. Morfaux,[33] who was evidently unacquainted with Vitali's writings, propounded a similar theory in his thesis, but offered no suggestion as to the nature of the change which the pigment undergoes in the liver. It may be pointed out that this theory includes two distinct hypotheses, and even if we doubt the re-conversion of urobilin into bilirubin we may still accept the first proposition that the liver cells are capable of laying hold upon the urobilin in the circulation. That they do so is indeed shown by the presence of urobilin in the bile whenever this pigment is being formed in the intestine. Some at least of the urobilin waylaid by the liver is excreted unchanged by that organ. If urobilin were merely a reduction product of bilirubin its re-conversion into that substance would be comparatively simple, but no one has yet obtained bilirubin by the oxidation of urobilin, and, as has been pointed out, the change involved is of a much more radical nature. To this objection Vitali replies by dismissing the urobilin analyses made by Hopkins and myself as proving nothing, because the material analysed was in his opinion obviously contaminated by an organic iron compound, since some of the products yielded a trifling ash in which iron could be detected. In so doing he ignores the close agreement of the results obtained from both fæces and urine by three different processes and also the fact that the figures obtained from the products with ash agreed with those got from wholly ash-free specimens.

He made some interesting experiments upon dogs and obtained evidence of increased formation of bile pigment during the circulation of blood containing urobilin. The bile formed appeared more highly coloured and caused more absorption of the violet end of the spectrum, but the quantity of bile was not increased. No such results were obtained when a saline solution containing urobilin was substituted for blood. The obscuration of the violet end of the spectrum, upon which Vitali chiefly relied as evidence of an increased formation of bile-pigment, was shown not to be due to an excess of urobilin as such. Moreover, he could obtain no evidence that the presence of urobilin caused hæmolysis or had a cholagogue effect. It is, however, clear [illegible] ed before so remarkable a [illegible] urobilin into bilirubin in [illegible] stablished fact. Riva[31] objects to this theory that in cases of cirrhosis and carcinoma hepatis the intestinal as well as the urinary urobilin is conspicuously increased, a fact of which the theory takes no account. To this Vitali replies that the increase of intestinal urobilin in such cases is not constant, and when present may be *ascribed to excessive hæmolysis and increased excretion* of urobilin in the bile [illegible]

[33] Recherches sur l'Urobiline, Paris, 1899.

These two hepato-intestinal theories embody the only attempts yet made to explain what is a very real difficulty in connexion with the intestinal theory. It is, of course, possible that both are to some [illegible] the liver is felt both [illegible] cycle. As has been [illegible] ed, urobilin is changed in [illegible] suggests that it may be [illegible] uggestion will be again referred to when we come to speak of that pigment.

One more objection must be mentioned. Urobilinuria is not infrequently [illegible] obstructed and th [illegible] diminishing. In [illegible] antecedent urobil [illegible] sidered. However, Vitali records a case in which this could be excluded and explains the facts by supposing that the [illegible] other hand, suggests that the partial removal of the antiseptic influence of the bile encourages bacterial activity, and that in spite of a diminishe [illegible] yield of urobilin is increased. [illegible] in such cases would supply [illegible] point [illegible]

There remains [illegible] are sources of uro [illegible] Its disappearanc [illegible] occluded shows that no such second process is usually at work and disposes of *the theory that urobilin is formed* from bilirubin in the tissues a [illegible] stances although the tissues [illegible] the excretion of urobilin is [illegible] some, and notably Gerhardt, [illegible] formation of urobilin from hæmoglobin cannot be excluded, although the urobilinuria which accompanies hæmolysis and *the absorption of extravasated blood may be explained* by the increased formation of bile-pigment which is known to take place under such circumstances. If it can be shown that in some cases of occlusion of the common bile-duct of sufficient standing to allow of the excretion of all absorbed urobilin urobilinuria is still observed, there is no alternative but to admit the existence of a second source. I have never met with such a case, and the only recorded instance of the kind with which I am acquainted is one referred to by Gerhardt of a patient the complete occlusion of whose bile-duct by carcinoma was verified post mortem, who developed hæmorrhagic ascites, and whose urine showed a pronounced urobilin band. It is not stated how long the intestinal contents had been practically urobilin-free at the time of observation. Beck injected blood under the skin of a dog with ligatured common duct and a biliary fistula and found a little urobilin in the bile, very little in the urine, and none in the fæces. Hence he concluded that the possibility of hæmatogenous urobilinuria could not be dismissed offhand, and it is evident that further observations are necessary before the question can be regarded as definitely settled.

Lastly, it is necessary to say something of the clinical aspects of urobilinuria. Increased excretion of the pigment, evidenced by a dark absorption band seen when the urine is examined with the spectroscope, is a very common phenomenon in disease, and we may distinguish between cases in which the band is seen for only a few days in succession and those in which it is present over a long period. A distinction may also be drawn between cases of what may be called "pure urobilinuria" in which a markedly increased urobilin excretion is the only obvious pigmentary abnormality and those in which uroerythrin and hæmatoporphyrin are also present in excess. In febrile disorders of almost every kind temporary urobilinuria may be met with, the duration of which usually corresponds with that of the pyrexia. In diseases of the liver the urobilinuria is usually persistent, as is well seen in cases of cirrhosis, malignant disease, or passive congestion secondary to cardiac or pulmonary troubles. In such cases the urobilin band is apt to be masked to some extent by a general absorption of the violet end of the spectrum due to other pigments. In diseases attended by excessive hæmolysis, and during the absorption of extravasated blood, there is apt to be conspicuous urobilinuria, and unless complications are present there is no corresponding increase of uroerythrin or hæmatoporphyrin. Such urines have a warm orange colour, which is readily recognised by a trained eye, and at the apex of a conical glass a pinkish tinge is usually seen. The occurrence [illegible] stent urobilinuria in pernicious anæmia was first [illegible] by Dr. F. W. Mott[35] and Dr. William Hunter,[36] and [illegible] es a diagnostic sign of real value and affords an indication of the progress of the case. In association with it I have observed a marked excess of urobilin in the fæces. When blood extravasations are being absorbed a temporary urobilinuria is apt to occur in a day or two after the occurrence of the hæmorrhage, and this again [illegible] y prove of service in the diagnosis of deep-seated [illegible] morrhages, such as pelvic hæmatoceles. Diminished [illegible] cretion or absence of urobilin from the urine may be due [illegible] diminished formation of bile-pigment, as in chlorosis, phosphorus poisoning, or acute yellow atrophy of the liver; to suspension of *urobilin formation in the intestine*, as in typhoid *fever* with green stools; as well as to occlusion of the common bile duct. Viglezio[37] suggested that renal permeability has an important influence upon the excretion of this pigment, and it is a clinical fact that albuminuria and urobilinuria very seldom co-exist. There is, moreover, experimental evidence in support of this view. As might be expected *all diseased kidneys do not hold back urobilin to* the same extent, and Zoja thinks that a parallelism may be traced between its excretion and that of urea. Morfaux,[38] who, with Achard, has recently worked at this subject, states that a kidney which is impermeable to methylene blue is impermeable to urobilin also, and that the more diffusible chromogen may pass through a kidney which does not allow the passage of the formed pigment.

HÆMATOPORPHYRIN.

When we pass to the consideration of urinary hæmatoporphyrin and of the pathological significance of its presence in excess we enter upon comparatively little-trodden ground. Hæmatoporphyrin has been found by MacMunn in the integuments of certain invertebrata, some of which have no hæmoglobin in their blood. *Krukenberg and Sorby* have shown that it is one of the colouring matters of the shells of birds' eggs, and Tappeiner found it in the bones of certain diseased swine. Pigments very closely resembling it have been obtained by the action of reagents upon substances other tha [illegible] Such are the turacoporphyri [illegible] the copper-containing pigment [illegible] prepared by Schunck and Marchlewski from chlorophyll. In normal human urine hæmatoporphyrin is present in minimal quantity, as can readily be demonstrated by appropriate methods. In many morbid urines it is found in larger but still small amounts, and under exceptional circumstances, and especially as a result of the administration of sulphonal, it is much more abundantly present in urines which have a deep port wine tint. However, such urines owe but little of their peculiar colour to this pigment. In the fæces it is also present, as Stokvis[39] has recently pointed out, and its presence may be demonstrated by a method employed by Saillet[40] for its detection in urine, the basis of which is extraction with acetic ether after the addition of acetic acid. I have recently made a number of examinations of the solid excreta rich orange-yellow. With zinc chloride and ammonia a brilliant green fluorescence appears, and the band is shifted towards red, as that of urobilin is under like conditions. The process can be stopped at this point by the simple addition of water, for aldehyde has no such action upon aqueous solutions of urochrome. If, however, the action be allowed to continue a further change ensues; the liquid reddens and a second band appears in the violet. The fluorescence can still be obtained with zinc chloride and ammonia, and both bands are shifted towards red and are closer together than before. This reaction with aldehyde affords a very delicate test for the presence of urochrome in alcoholic solutions. The product of the earlier stage, although it is not identical with urobilin, resembles that pigment quite as closely as the products obtained from bilirubin and hæmatin by the action of reducing agents; but no second band is developed when aldehyde is added to an alcoholic solution of urobilin. On the other hand, by the action of potassium permanganate upon urobilin Riva and Chiodera[56] obtained a substance closely resembling urochrome, and a similar product is formed when an aqueous solution of urobilin containing ether is evaporated upon a water bath. Neither product shows any absorption band and both behave as urochrome does when it is acted upon by aldehyde. Riva and Chiodera also detected the presence of urochrome in fæces and in serous effusions, and its presence in both may readily be demonstrated. I have found that the most satisfactory method for its detection in fæces is to extract with a saturated solution of ammonium sulphate, which takes up neither urobilin nor its chromogen. From the yellow extract so obtained the urochrome can be separated with alcohol in the ordinary way,[57] and precipitated from alcoholic solution by ether. Its identity can be established by means of the aldehyde reaction. As judged by the colour the quantity obtained is small and there is no relative excess in the intestine, as in the case of urobilin.

When ascitic fluid is saturated with ammonium sulphate the serum pigment is all thrown down with the last of the proteid precipitate, and from the almost colourless filtrate alcohol extracts a minute amount of a yellow pigment, which yields the aldehyde reaction of urochrome. Riva's[58] suggestion that some of the urobilin absorbed from the intestine may be converted into urochrome in the tissues is in part based upon the scanty pigmentation of the urine of young infants and in part upon the almost complete decolourisation of the urine of a patient with obstructed bile duct, when the bile-pigment was removed by means of baryta mixture. The case or cases which he observed were certainly exceptional in this respect, for in the urine of several patients with occlusion of the bile duct, which I have examined I have never failed to find abundance of urochrome present after similar treatment. Vitali has had the same experience, and it is a well-known fact that in cases of biliary fistula, with occluded duct, the urine is not decolourised even after it ceases to contain bile-pigment. Moreover, urochrome is present in the urobilin-free fæces and even in those of infants with congenital atresia of the ducts. One is, therefore, driven to conclude that the formation of urochrome is quite independent of that urobilin, and although it is probably a derivative of hæmoglobin there is as yet no evidence to show how or where it is formed. It may be mentioned as a negative point that the excretion of urochrome is not obviously affected by removal of the spleen.

Clinical evidence bearing upon this question is at present wholly wanting, and although there can be little doubt that the excretion of urochrome is subject to wide fluctuations apart from the apparent variations due to concentration or dilution of the urine, we know nothing of the conditions under which they occur. The pigment has no characteristic spectrum and the want of a satisfactory method for its estimation makes it difficult to form even a rough notion of the quantity present in morbid urines, in which its colour is so often masked by that due to other pigments.

UROERYTHRIN.

Of the mode of origin and the relationships of uroerythrin we know even less, notwithstanding that its power of imparting a pink colour to urate sediments renders its detection extremely easy and caused it to be the first of all the urinary pigments to attract individual attention. Uroerythrin is a potent colouring matter, far excelling urochrome and urobilin in this respect, so that the presence of even a small amount has a conspicuous effect upon the tint of the urine in which it is contained. The peculiar reddish-orange colour of the pigment in solution contrasts strongly with that of the pink urate sediments, in which it probably exists in combination, for they show a characteristic spectrum of their own.[59] In its properties uroerythrin differs widely from the pigments which we have hitherto been considering. The most conspicuous of these is its extreme instability, and compared with it urobilin and hæmatoporphyrin are quite stable compounds. Its solutions in alcohol or chloroform are very rapidly decolourised by light, and even when kept in the dark quickly undergo change. Alkalies destroy the pigment readily, with the production of a green tint. Neutralisation of the alkali does not restore the original colour or bring back the absorption spectrum, which is characteristic though ill-defined, consisting of two feeble bands in green and blue united by a feebler shading. One of these bands has the position of the urobilin band, but both alike disappear when the solutions are decolourised by light. These properties suggest that uroerythrin is a pigment of a different order from those which we have hitherto considered and that it is probably not a member of the family of hæmoglobin derivatives. There is, however, little to guide us in this matter and C. E. Simon[60] quotes an estimation of the carbon and hydrogen in uroerythrin which is suggestive of a relationship to bilirubin, but he gives no particulars. Hitherto this pigment has only been found in urine and there is no evidence that it is excreted in the form of a chromogen. On the other hand, it may fairly be doubted whether a substance so readily destroyed by alkalies can exist as such in the alkaline body fluids. I have sought for it in the fæces of patients in whose urine it was abundantly present by several methods, such as extraction with amylic alcohol and acetic ether, both excellent solvents of uroerythrin; by shaking water extracts, acidified with acetic acid, with amylic alcohol, and by precipitation of crystalline uric acid in watery extracts. All of these methods have failed to reveal its presence and although some method as yet untried may reveal traces it can hardly be present in any considerable amount in the solid excreta.

Although uroerythrin is probably not a strictly normal constituent of urine it may appear in connexion with most trifling deviations from the standard of health. Heller[61] regarded it as the commonest of all abnormal ingredients of urine, and uratic sediments are not often entirely free from a pink tint which may, however, only be visible after their removal by filtration. Such knowledge as we possess of its pathological significance is entirely derived from clinical observation and points to disturbances of the hepatic functions as the prime causes of the increased excretion of uroerythrin. Urines which throw down intensely pink uratic sediments or have the fiery orange colour indicative of much uroerythrin in solution are most frequently passed by patients with definite hepatic diseases such as cirrhosis, carcinoma, or the passive congestion resulting from cardiac lesions. It is true that this pigment is often excreted in large amount in certain febrile disorders, such as acute rheumatism and pneumonia and also in gout, and when associated with an undue excretion of hæmatoporphyrin it affords additional evidence of the implication of the liver. In typhoid fever a large excretion of uroerythrin is exceptional and its occurrence has been connected with pulmonary complications. Riva has made the interesting observation that in such diseases as cirrhosis hepatis the excretion of uroerythrin, as also of urobilin, is much diminished when the patient is put upon a milk diet In nephritis uroerythrin is seldom found in the urine, but I have seen in a case of pneumonia an abundant excretion of this substance accompanying conspicuous albuminuria.

If uroerythrin in urine is always indicative of hepatic disorder it is clear that not only actual disease of the liver, but even functional disturbances of the slightest description, such as may be supposed to result from trifling errors of diet or may accompany a dyspeptic attack, suffice to bring about its appearance.

Although, as we have seen, the liver plays so important a part in connexion with the pigmentation of the urine, the various morbid changes to which that organ is liable have somewhat different effects upon the excretion of the several pigments, and it is probable that a more detailed study of these effects would supply further diagnostic indications. However, in this review of a somewhat obscure branch of chemical pathology nothing has been further from my desire than to claim for my subject an exaggerated practical importance or to suggest that the investigation of the urinary pigments should form part of the routine of clinical examination. Such importance as the subject possesses is derived from the light which it throws upon processes which are at work in the body both in health and in disease, and especially upon those which are concerned with the disposal of effete blood pigment. Nevertheless, in certain cases the examination of the colouring matters of the urine may afford information of real diagnostic value and which is not readily obtained in other ways. It may therefore be fairly claimed that their study is one which is not simply and solely of academic interest.

A Clinical Lecture

ON

EMPYEMA FOLLOWING LOBAR PNEUMONIA

Delivered at Guy' Hospital on June 27th 1900,

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,

PHYSICIAN TO, AND LECTURER ON MEDICINE AT, THE HOSPITAL

GENTLEMEN,—Most patients suffering from lobar pneumonia either recover or die without any complications, but among those few in whom complications follow there are none for whom you can do more than for those who suffer from empyema. A few years ago Dr. Chaning Pearce helped me to abstract several cases from our medical reports; lately my clinical assistants, Mr. F W. Goble and Mr. B. W. Moss, kindly abstracted some more, and I have abstracted some myself. Altogether there are 45 15 of these were under my care and for permission to refer to the others I am indebted to my colleagues. The results are shown in the following table:—

—	1898	1897	1896	1895	1894	1893	1892	1891
Total number of cases of lobar pneumonia in Guy's Hospital ..	122	115	114	100	67	182	88	108
Number of cases of pneumonia complicated by empyema	3	7	3	6	2	9	2	6
Percentage complicated by empyema	2·46	6·08	2·63	6·0	3·0	4·94	2·27	5·5

—	1890	1889	1888	1887	1886	1885	1884	1883
Total number of cases of lobar pneumonia in Guy's Hospital ..	83	60	43	72	48	39	26	69
Number of cases of pneumonia complicated by empyema	1	1	1	2	—	—	1	1
Percentage complicated by empyema	1·13	1·6	2·3	2·9	—	—	3·8	1·4

If we divide this period of 16 years into two equal periods we find that in the eight years 1891–98 there were 896 cases of lobar pneumonia, of which 38, or 4·24 per cent, had empyema, while in the eight years 1883 to 1890 the total number of cases of pneumonia was 445, among which there were seven cases, or 1·57 per cent, of empyema. Thus we see that both relatively and actually the number of cases of empyema due to pneumonia has increased of late years, and the rarity of this complication a few years ago explains the fact that in many text-books published then it was not mentioned that empyema was a complication of pneumonia, and it also goes to confirm what I think experience tells us—namely, that pneumonia is a more severe disease than it was

muc

figur

have been very great during the last eight years, but the frequency of empyema has increased. There is very little doubt that these figures understate the number of cases of empyema following lobar pneumonia, for it is almost certain that some of the patients who are admitted for pus in the chest have had pneumonia shortly before they came into the hospital Only recently a man was under my care for empyema which was opened. He died very shortly after the operation and pneumonia was found at the post-mortem examination. Had he recovered we should not have known that his empyema was consecutive to pneumonia. Another reason which makes it impossible to give precisely the proportion of cases of pneumonia which are followed by empyema is that the pneumococcus may be the means of setting up an empyema, even although it does not induce pneumonia, and in such a case the general symptoms and physical signs may be such that it is very difficult to deny certainly the presence of pneumonia. I have seen three or four cases illustrating this point; perhaps the best is that of a man who was under my care but whose case is recorded by Dr. J. W. Washbourn in the Transactions of the Royal Medical and Chirurgical Society, vol. lxxvii. The patient was aged 36 years; his illness was ushered in by a rigor, he had persistent high temperature, rapid breathing, cough, herpes, and delirium. His general aspect was so like that of a patient suffering from pneumonia that both the medical registrar and I pointed him out to the students as having the exact appearances of a patient suffering from pneumonia. The physical signs were until the day before death those of solid lung—viz., loud bronchial breathing, bronchophony, dulness, and consonating râles. Not until the day before death did signs of fluid appear at the base of the lung. At the necropsy the lung was normal both to the naked eye and the microscope, 54 ounces of pus were found in the chest, and this was proved by microscopical examination, by cultivations, and by inoculations to contain no micro-organisms but pneumococci It is of great interest to notice that such cases as these remind us that although the pneumonia due to the pneumococcus does lead to a pulmonary abscess, yet the same micro-organism may do so when it invades other parts of the body.

We see, therefore, that it is impossible to state with accuracy the percentage of cases in which pneumonia is followed by empyema, but it

of 325 consecutive cases of

of Guy's Hospital there were

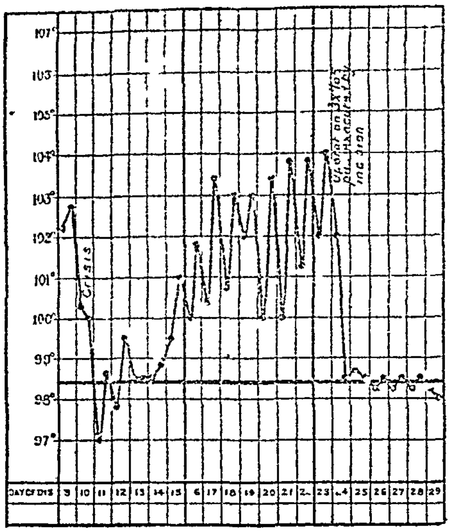
it appeared that the empyem

But although this is so, it is easy by systematic examination of the pus to find out the proportion of cases of empyema due to the pneumococcus I have not searched through all our records to find the exact proportion, for several authors have published results from which it appears that the pneumococcus is a very common cause of empyema, probably the commonest, that it is especially common as a cause in children, some considering that 75 per cent. of all empyemata in children are due to it.

Perhaps the best way to consider the subject is to see what we can learn from the 45 cases of empyema following upon lobar pneumonia which occurred in Guy's Hospital from 1883 to 1898 and to check the knowledge thus gained by the patients now in the hospital and one who has recently died.

By far the most important aid to diagnosing that empyema has followed pneumonia is the temperature. The usual thing, if empyema follow, is for the temperature to fall when the crisis takes place, for it to remain down two or three days, for it then to rise again, so that it soon becomes from 2° to 4° or 5° above normal in the evening and about 1° or 2° in the morning; this continues until the pus is evacuated. Chart 1, taken from a patient under the care of Dr. Frederick Taylor, shows this admirably Sometimes the apyrexial interval is only one day, sometimes it is four or five days, and sometimes there is not strictly an apyrexial interval, for the temperature does not fall at the crisis to normal, but only to nearly normal, and then soon begins to rise again, so that instead of an apyrexial interval we have an interval of lower temperature There is a fall of temperature at the pneumonic crisis with a subsequent rise in about a third of all the cases in which empyema followed pneumonia This fall of temperature is a very curious phenomenon, for we believe the pneumonia to be due to the pneumococcus and the empyema to be due to the same micro organism, and that it is in some way responsible for the pyrexia; that being so it is difficult to understand why, although these micro-organisms are constantly present, there should be any fall of temperature, for there may be a well-marked crisis with an apyrexial interval before the onset of the temperature indicating empyema even in cases in which the pus from the empyema contains no micro-organisms save pneumococci. Also it is difficult to understand why, when the temperature is indicative of the invasion of the lungs by pneumococci, the daily variations should not be extreme, but when the same micro-organism subsequently causes empyema the daily variations should be great.

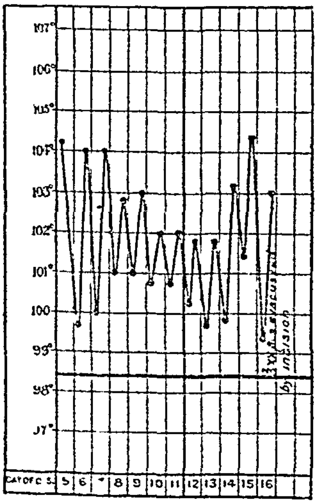
CHART 1



Showing the most common course of the temperature in empyema after pneumonia.

In many cases there is no apyrexial interval and probably in some of these pus is present from quite early in the illness. Chart 2, from a patient under the care of Dr. Taylor, shows very well a case in which there was no interval during which the temperature fell. You must be particular to bear in mind that there is no sharp boundary line between the two groups, for the temperature may fall a little about the end of the first week, but the fall may be so slight that it is impossible to say whether it represents a crisis modified by the presence of pus.

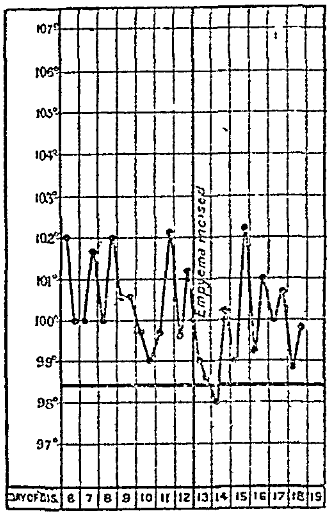
CHART 2



Showing the temperature from a pneumonic empyema without any apyrexial interval.

There is a third group in which also there is no interval during which the temperature is lower, but in which there is some complication present that may well explain this. Pericarditis and malignant endocarditis may both of them be associated with empyema after pneumonia and if they are present early in the case they may prevent the fall. Chart 3 represents the temperature of a boy now in John Ward under my care and as in his case there is pericarditis as well as empyema it is probable that this explains why he did not have a more definite crisis and why even when the empyema was opened the temperature did not fall. It is noteworthy that although pericarditis is a common complication of pneumonia and five of our cases of empyema had pericarditis, yet pyopericardium is so rare. Only one of our 45 cases showed it, and in this case, which was not diagnosed during life, 23 ounces of pus were contained in the pericardium and 12 ounces in the right pleural cavity. Although the empyema in the little boy (Chart 3) now in John Ward lay against the pericardium and he had pericarditis there is no evidence that he has had pyopericardium. Pus in the pericardium from any cause is very rare. I think we have only had six instances at Guy's Hospital in 11 years.

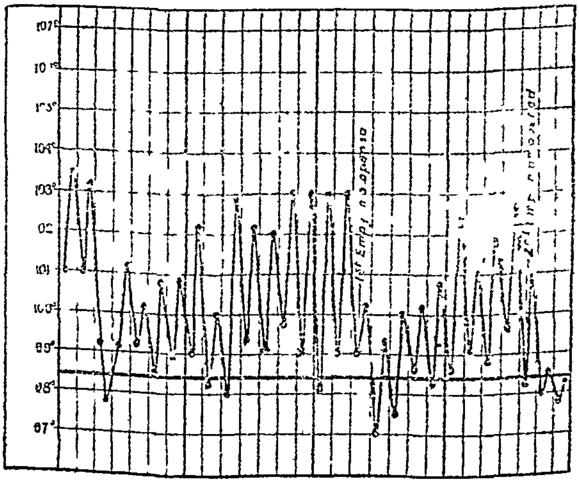
CHART 3



Showing that if pericarditis is present the opening of the empyema may hardly influence the temperature.

Three of our 45 cases developed pneumococcal malignant endocarditis; in one of them, although there was no lesion of the valves, there was general infection as shown by the presence of infective aneurysms. In a fourth case there was a pneumococcal gluteal abscess and in a fifth there was pneumococcal inflammation about the ankle. It is obvious that any of

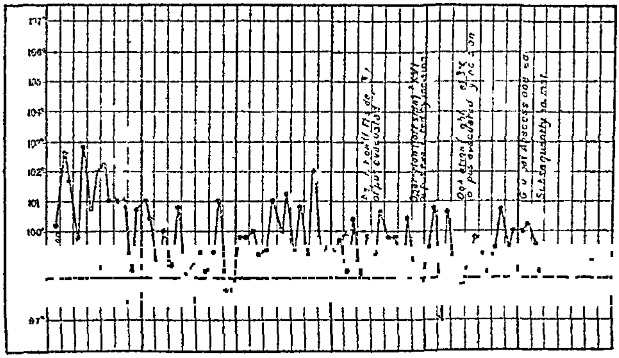
CHART 4



Showing the temperature in a case in which two empyemata were opened by incision.

these will mask the temperature due to the empyema There really appears to be no part of the body in which the pneumococcus may not flourish, you know it will cause meningitis, peritonitis, and arthritis In very rare instances there are two empyemata, then although the first is operated upon the temperature does not fall permanently until the second is opened Chart 4 from a patient under the care of Dr E O Perry, shows this very well, and Chart 5, from a patient under the care of Dr P H Pye Smith, shows a case in which there was a post pneumonic empyema at each base and an at [illegible] was not until all had been [illegible]

CHART 5



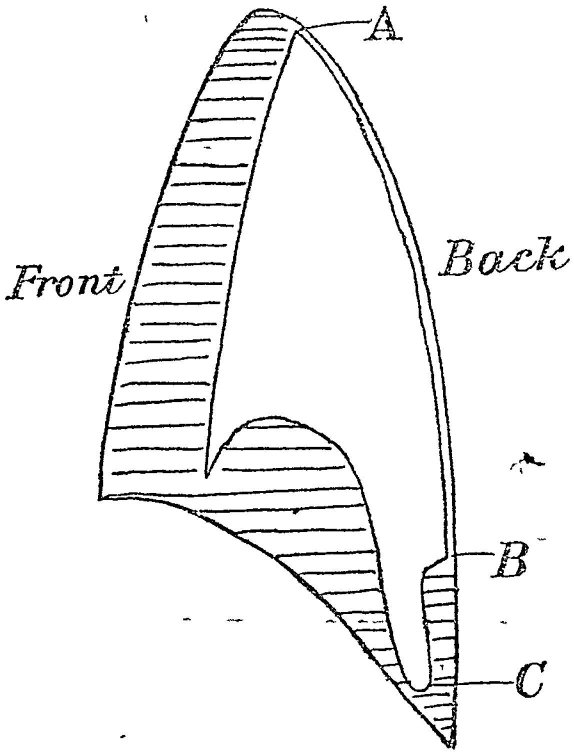
Showing the course of the temperature in a case in which a double empyema and gluteal abscess existed

Althou [illegible] ure is most important in helping you to diagnose an empyema following pneumonia it is not an infallible guide, for in the first place the temperature may remain up for some time and yet no pus be present Crisis occurs in only about half of all the cases of pneumonia and when there is no crisis the temperature sometimes falls irregularly and tediously; this is well exemplified by a boy now in No 3 bed John Ward Usually such temperature receives no explanation from the condition of the patient, but it is to be noted that these irregular unexplained temperatures which may, especially in children, follow upon pneumonia do not often show the considerable daily range which is so suggestive of pus, but, on the other hand, as we shall see directly, pus may be present without any wide daily range Sometimes the persistent temperature after pneumonia is due to some other complication—e g , malignant endocarditis—and not to empyema or it may be due to some associated disease such as typhoid fever Again particularly in children, it is very difficult always to tell lobar pneumonia from broncho pneumonia, and in this the temperature may remain up irregularly for a long time, or pyrexia may be caused by quite a small empyema which is coughed up and never detected In the second place, an empyema in quite exceptional cases follows pneumonia with little or no rise of temperature to reveal its presence In one of our 45 cases the temperature slowly fell to normal, but the signs of a localised collection of fluid below the left clavicle remained and an exploring needle revealed a localised empyema In a patient under my care pneumonia was complicated with pericarditis The patient was taken ill on Sept 23rd, by Oct 15th she was much better, but from then till Nov 6th her temperature was usually raised a degree in the evening From Nov 6th to the 12th it was about 101° F in the morning and 103° or 104° in the evening A small empyema containing four ounces of pus was found Perhaps in this case the empyema had been present all the time although for three weeks the temperature was only raised a degree In another patient, whom some of you saw not long ago there were two or three pints of pus but the temperature was usually only between 99° and 100° I have carefully compared the respirations in several cases, but I have not made out that rapidity of respiration is much help in diagnosis, but there is some slight evidence that when the empyema is due to the pneumococcus the respiration may occasionally be more rapid than either the fluid or the temperature would lead us to expect

Let us now pass on to the examination of the chest, and in the first place let me direct your attention to the great importance of local tenderness Very often people with deep seated small abscesses have one spot pressure upon which with the finger gives rise to a slight feeling of pain Such a spot, if present should be chosen for insertion of the exploring needle and may enable you successfully to find pus that would otherwise probably have been missed I have seen attention to this lead to the discovery of a small suppurating hydatid, small subdiaphragmatic abscesses, and small localised empyemata

There is little to be said about the physical signs Pus gives the [illegible] and exper [illegible] small emp [illegible] layer of lymph and they have much solid lung in their neighbourhood The smallest post pneumonic empyema I have detected during life only contained half an ounce of pus and it is common for them to hold only three or four ounces Sometimes it is the absence of air entry, sometimes it is the percussion note and sometimes it is the absence of bronchophony that particularly guides you In some cases the difficulty is greatly increased by the fact that the empyema is localised and deep in the chest, thus I have seen it sub diaphragmatic and I have seen it between the lobes of the lung There is at the present moment a boy in John Ward (No 14) whose widely oscillating temperature following upon an ordinary attack of pneumonia makes it almost certain that he has an empyema When we examine the chest we find that signs suggestive of fluid can be obtained just against the vertebral border of the scapula when it is well dragged forward but there are none in the axilla We have repeatedly tried, and always failed, to reach this empyema with an exploring needle Probably it is a small one well under the scapula and perhaps between the lobes of the lung Twice I have known a small empyema successfully and easily found with an exploring needle although when later the patient has been under the anæsthetic the surgeon has failed to find it till he has made nearly 20 punctures, and I have seen small empyemata in the post mortem room which had during life been missed, although the exploring needle had been inserted many times There is no royal road to finding them—the only thing is to take an infinitude of pains One reason why they are so difficult to discover is that as often as not adhesions shut off the pus in irregularly shaped cavities The most striking instance I have ever seen of these adhesions is that of a man who was admitted into Philip Ward last March (See Fig 1) He gave a history of two years illness and said that he had been worse lately, but even when questioned would not admit that he had been suddenly taken ill or had had a rigor. His temperature varied between 99° and 100° F., he had much diarrhœa and albuminuria, and he was anæmic and hectic-looking. Both sides of his chest moved equally.

FIG. 1.

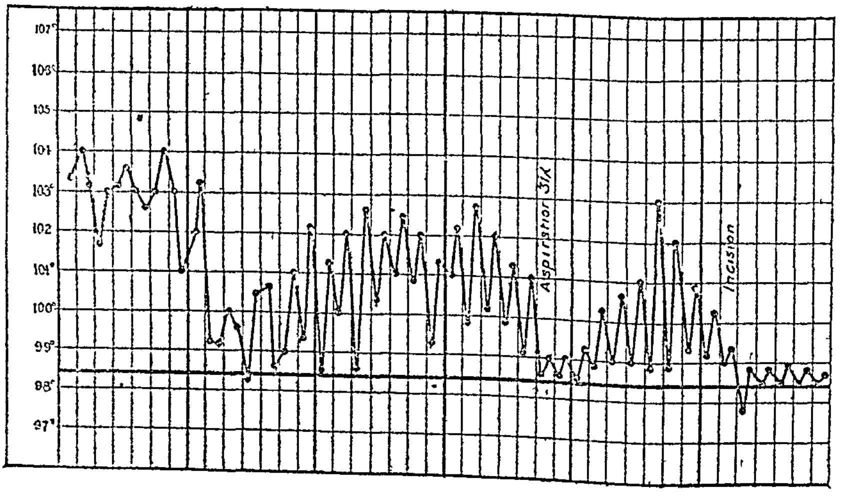


A diagram of an antero-posterior section through the left chest, showing the shape of the empyema which is indicated by horizontal lines From A to B the lung was firmly adherent to the chest wall. From B to C it was compressed. Most of the rest was pneumonic.

The left side was dull in front with a poor air entry, behind it was also dull with a poor air entry and some bronchial breathing. Below the tenth rib base it was especially dull, so that I inserted a needle in the tenth space and withdrew pus; and in order to prove that the whole of the dulness behind was not due to fluid I inserted the needle again in the ninth and eighth spaces without obtaining any pus. There was a loud pleuritic rub and some rhonchi on the right side. I concluded that the case was one of phthisis with a tuberculous empyema at the base of the left lung and finally decided to open it. About four pints of pus gushed out and the patient died very shortly afterwards. We found that he was suffering from a huge post-pneum[illegible] was still in a state of grey [illegible] commenced apparently be[illegible] lung and the diaphragm and strong but recent pleuritic adhesions running vertically down in and behind the mid-axillary line had localised it so that it spread up the front of the chest right up to the clavicle but only up the back as far as the tenth rib. The diagram shows an antero posterior section through the left chest. Had we known that there was so much pus it would have been wiser to slowly aspirate before opening the chest, for probably the sudden taking away of all that fluid from around the heart led to the sudden death. It is interesting to note that there was a small abscess in the lung. I have seen that in at least one other case of pneumococcal empyema, and it is also worthy of note that although there was all this pus there was no œdema of the chest-wall, for it is said that œdema of the chest-wall never occurs with pneumococcal empyema. The pus that is let out of these pneumonic empyemata is often light green and very thick; you can notice this very well in the little boy in John Ward; he coughs out thick pellets of almost solid greenish pus.

Much discussion has taken place about the treatment, for it has often been stated that when the pus contains a pure cultivation of pneumococci aspiration will suffice and incision is unnecessary. Simple aspiration has been tried in several of our 45 cases, but always in a few days the temperature, which at first fell after the aspiration, has begun again to rise and to assume a hectic type, and at the same time signs of fluid have reappeared. One or two very bad cases have died, but in most cases the chest has been ultimately laid open and the patient has done well. Chart 6, from a patient under the care of Dr. Taylor, shows these points admirably. Two patients who have been aspirated have refused to submit to any further operation and have consequently gone out of the hospital. One we have fortunately been able to trace and Mr. Moss kindly visited him at his home and reports that he is now quite well and that his chest seems healthy, although no incision has been made into it. His chart is No. 7. He was admitted under my care for pneumonia on Oct. 16th, 1897, and subsequently was under the care of Dr. Pye-Smith. Five ounces of pus were withdrawn on Nov. 20th. The temperature fell but soon began to rise again, so six ounces were withdrawn on the 28th. Again the temperature fell, but in a few days it rose again and showed wide daily fluctuations, and as he would not have anything more done he left on Dec. 12th, 1897—that is, two and a half years ago. Whether he has coughed up a small empyema it is impossible to say. In none of our cases did a single aspiration suffice to stop the pyrexia and formation of pus, although in some cases—as, for instance, that from which Chart 6 is taken—it was proved that the pus contained no organisms except pneumococci.

CHART 6.



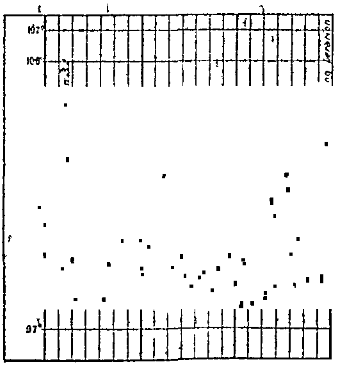
Showing the temperature in a case of post-pneumonic empyema which was aspirated and subsequently incised.

So we may conclude from our experience at Guy's

Hospital that it is very unlikely that simple aspiration will cure any case of pneumococcal empyema; still it must be remembered that a certain number of cases have been recorded in which it has appeared to be curative It seems to me that if the empyema is small it is wiser to evacuate it by incision, for if aspirated probably it will a week or so later have to be incised, and as it is small and will soon heal up it may as well be incised at o
is a large one it is better incised
out the pus to prevent cardiac
seriously and dangerously ill and
prolong his illness by aspiration, as that will almost certainly have to be followed by incision in a week or so Still, in certain cases in which the patient is not very ill and much objects to an anæsthetic or to an operation, you may at his wish try simple aspiration if the pus withdrawn by the exploring needle gives a pure cultivation of pneumococci It is said that children recover more often with simple aspiration than adults

Turning next to the prognosis I find that among our 45 cases 13 died, giving a mortality of almost 29 per cent

CHART 7



Showing the temperature in a case of post-pneumonic empyema which was aspirated twice.

This is considerably higher than that given by some authors, but then it must be remembered that children—in whom the prognosis is most favourable—often go to a children's hospital, so that a large general hospital does not get a fair proportion of patients under 10 years of age, and further, four of the 13 had signs of general infection as shown by malignant endocarditis or infective aneurysms and two were instances of pneumonia occurring in those patients who were already the subjects of phthisis If we deduct these six cases we get a mortality of seven among 39 cases, or about 18 per cent The mortality among patients suffering from pneumonia varies widely in different years Thus at St Thomas's Hospital[1] in 1887 it was 35 per cent in the latter half of 1888 and in the first nine months of 1889 it was 9 per cent, and in 1882 it was 7 per cent, but in January and February when influenza was rife it was 64 per cent It is thus impossible with the figures at our disposal to say how far the danger to life is, in pneumonia, increased by empyema but certainly the extra danger is not very great In one of the cases of empyema with malignant endocarditis this was more marked on the right side of the heart than on the left, suggesting that the infection had taken place from the pleura by means of the azygos veins

It has been stated that recovery usually follows when a pneumonic empyema bursts into the lung, and our series contains a very striking case which goes to support this view. A very feeble man aged 72 years, was admitted under the care of Dr J F Goodhart suffering from pneumonia An empyema formed at the base of the right lung, five ounces of pus were let out by incision, but the patient was no better, a few days later he coughed up several ounces of pus by the mouth; he at once began to mend and made an excellent recovery I have also seen a patient whose case is not included in our series cough up a post pneumonic empyema and get perfectly well, and I am afraid that we must leave the boy in John Ward, whose empyema is probably deep seated somewhere under the scapula, to get well in the same way; indeed, if it is deep between the lobes of the lung probably he will get better more quickly if he coughs it up than if we find it and open it

The amount of pus found in these empyemata is most variable; 170 ounces were present in one of the patients who had malignant endocarditis The rate at which it is poured out must be great, for if in the cases in which 80 and 72 ounces were respectively found we believe that the formation of pus began with the onset of the pneumonia at least five ounces must have been formed daily, and if we consider that the pus did not begin to be formed until the secondary rise of temperature began the rate of collection must have been half a pint a day In striking contrast to these is the case already mentioned in which only half an ounce was found, although 24 days had elapsed since the secondary rise began Rapid as is the rate at which pus may collect in the chest there is no evidence that it can collect at the rate at which clear fluid may be poured out, for I have recorded a case in which over 100 ounces of this were secreted in one and a half days[2]

An Address

ON

THE PHYSIOLOGY AND PATHOLOGY OF INHERITANCE, OR WHAT DO WE INHERIT FROM OUR PARENTS?

A Lecture Introductory to a Course of Clinical Medicine delivered in the Newcastle upon Tyne Royal Infirmary on Oct 31st, 1900,

BY THOMAS OLIVER, M A DURH, M D GLASG
F R C P LOND.,
PHYSICIAN TO THE NEWCASTLE UPON TYNE ROYAL INFIRMARY AND PROFESSOR OF PHYSIOLOGY AT THE COLLEGE OF MEDICINE, NEWCASTLE UPON TYNE.

GENTLEMEN,—From a biological point of view "we are the heirs of the ages" Not only in the sense that we are participators of the accumulated experience of the race, but in the physical and mental endowments that belong to each of us, do these words find scope for their realisation Studying together, as we shall this winter, clinical medicine, it has seemed to me that the present is not an inopportune time to draw your attention to some of the less frequently discussed problems that underlie human life in health and disease If I can show you that disease is not a morbid entity, requiring to be diagnosed and treated, but something more, and that into our conception of disease there must enter, in addition to the symptoms complained of and the physical signs of ill health, knowledge of the individual with his peculiarities of constitution his susceptibilities his age and his occupation—in a word, that it is not disease as disease but the individual with his malady that requires treatment—the time at our disposal will not have been misspent

Disease, from the words "dis" and "ease," simply means want of ease In health all our organs functionate without impressing themselves upon our consciousness, but in disease we are often too painfully aware of their existence It was the opinion of the ancients that disease depended upon a chemical change in the humours of the body, and so for a period the humoral pathology prevailed, remnants of which are still seen in the nomenclature of disease Later disease was thought to be due to a distinct and tangible cause, a *materies morbi*, while subsequently to this it was regarded as the last link in a chain of processes of deranged metabolism and abnormal function with diminished resistance to external surroundings Within the last two decades, owing to the great strides made by bacteriology—a science which has shown that many diseases, especially those of an infectious nature, and even others that are not appreciably infectious, are due to the entrance into the system of microbes—medical opinion as to the cause of disease has veered round to a belief in the existence of a *materies morbi*. Even here there is danger in being too exclusive. Admitting that tuberculous disease, for example, is bacillary and that there is no tubercle without Koch's bacillus, and also that pneumonia and erysipelas are equally caused by micro-organisms, it is for us to consider whether other factors are not in operation and to assign to each its respective rôle.

---

[2] THE LANCET, March 25th, 1893, p. 6.9

Leaving out of consideration congenital affections and deformities, or those abnormal conditions with which a child is born attributable to circumstances operating directly upon the fœtus in utero, as in congenital syphilis, I shall deal with those individuals who are born presumably healthy and yet in whose system there are such refinements of structure and deviation from the normal that as time goes on life is brought prematurely to a close by disease similar to that from which one or both parents perhaps died, or during whose lives there are exhibited traits of character or peculiarities of temper and of disposition that recall the life of the parent or of an earlier ancestor. I eliminate congenital syphilis and congenital tuberculosis, for in these the actual disease is simply passed on to the offspring and assumes in it the same activity as it did in the parent. In the inheritance of which I speak it is not disease, but simply a susceptibility, that is transmitted.

How, then, can I best illustrate the physiology of inheritance? Galton in his book on "Hereditary Genius" speaks of the child as being not simply the product of the two lives paternal and maternal, but also of the four grandparents and eight great-grandparents and so on, indicating that into the production of the physical constitution and mental qualities of a human being there enters more than is contributed by the immediate parents. The book is an attempt to show from the family history and biography of men distinguished in literature, in science, in legislation, in the profession of arms, and in law that the qualities exhibited by men which made them renowned depended less upon their education and surroundings and more upon the physical constitution and mental powers inherited from their parents or earlier progenitors. In one sense the teaching is depressing. We are what we are because we cannot be otherwise and we become what we are through inherited qualities. Human experience, on the other hand, shows that however much certain qualities may be inherited it is not always and alone thus that they come to us. Evolved in the course of time, they have been fostered by survival of the fittest, by marriage, and by education. If we add to patience, to zeal, and to capacity for work good health, then by the proper exercise of all our powers advancement in life must be secured. Social advantages, dogged perseverance in a particular calling, good manners, and ability to utilise opportunities make for success; yet, on the other hand, it must be admitted that when an individual is possessed of great natural ability or those qualities of intellect and disposition that urge to the performance of acts that lead to reputation it is almost impossible for him to have his progress thwarted either by the circumstance of lowly birth, by social disadvantages, or even by the defects of early education. By virtue of the gifts which he has inherited he overcomes all difficulties and therefore must come to the front. If there are inherited qualities that make for good, so, too, must there be others that make for harm to the individual, and it is this particular feature of inheritance that forms the theme of my discourse to day. When we ask ourselves the question, "What is it that is inherited?" we find it difficult to reply. A mother, for example, may transmit masculine peculiarities to her son which she herself does not exhibit, and it does not follow because a father and mother are highly intellectual that their child will also exhibit ability. The child, as already stated, is the offspring, not of the parents alone, but of earlier ancestors as well. Given intellectual parents, all we can say is that the chances are that their offspring will be gifted to a greater degree than children in whose family nothing beyond mediocrity has ever been attained. Ability clings to families, but in order that it may be displayed there must also be inherited capacity and zeal for work, for without these only a sorry figure will be cut in the world by the individual compared with what might be accomplished. We all know persons of this stamp—men who are extremely able, yet since they lack the other qualities they do not rise in life. The number of people must be few who would underrate the influence of early home training or the invaluable help rendered to a youth by a good and able mother. The natural ability of such a mother, finding but limited scope within the confined sphere of her maternal and domestic duties, causes her to stimulate her son to attempt a career and to achieve results which she herself could only aspire to in imagination; hence it is that able men are often the sons of clever women.

If it is true that mental gifts and physical powers are only obtained by inheritance, is no encouragement to be extended to mediocrity and no hope held out to men whose family records contain no names of sons eminent in science, in art, or in literature? To believe that one is destined to a great end is at once to command success, but there is another fatalism that leads to destruction. The age in which we live is one of keen international competition and the prize must ultimately belong to that nation which, possessing great physical vigour, natural resources, or acquired means of sustenance, finds its opportunity in equable development of mind and body, in adherence to right, in patience and persistence, and in the avoidance of all causes that lead to degeneracy, physical, mental, or moral. Evolution proceeds apace in nations as in individuals. It is from the lower ranks of life that the higher strata of society are filled. There is a continual moving upwards. New conditions, fresh surroundings, and unexpected difficulties stimulate men to rise, but behind all these facts there lies the plastic material upon the hereditary acquisition of which in its best form so very much depends. In a general way, then, we support the contention of the author of "Hereditary Genius." Galton's conclusions have not been allowed to pass without a challenge. Some writers maintain that mental ability is not the outcome of inheritance but of individual acquisition, that it is the result of the operation of such causes as education and external surroundings. Without throwing myself further into this discussion at present I shall try to find answers to some of the problems I have raised by going altogether outside the sphere of the human family, whose actions, ruled oftener by sentiment than by reason, cannot always be controlled, and see whether in racehorses whose pedigrees can be accurately traced and doings recorded Galton's theory finds support or not.

THE MODERN RACEHORSE.

So far as I know there is no instance on record of a horse that was not a thoroughbred ever having won the Derby. This circumstance is appealed to in order to demonstrate the superiority of blood and the transmission of racing qualities by careful mating of sire and dam. A certain amount of doubt surrounds the origin of thoroughbred horses in this country, but to the Darley Arabian which came from Aleppo to Aldby Park in Yorkshire *circa* 1705 to 1710 most authorities attribute the commencement of the breed. Others regard the Byerley Turk as the founder of the famous family, others again claim Godolphin and Flying Childers, but Godolphin came upon the scene 20 years after the Darley Arabian and Flying Childers was his own foal. It is the descendants of the Darley Arabian that form the renowned breed of English racehorses, whose speed for short distances is regarded as the outcome of inherited qualities and the result of careful in-breeding. It is an interesting fact that nearly every winner of the great races last year was a descendant of St. Simon who, although he never competed in the Derby, was yet the better horse, for he beat the Derby winner of his year. St Simon was from first to last an unbeaten horse. He did not run in the Derby owing to the fact that his breeder, Prince Batthyany, died while the horse was a yearling and the nomination therefore became void. The last race St. Simon ran in was at High Gosforth Park as a three-year-old, and this race he won easily. Shortly afterwards he retired with his splendid constitution to the stud and became the progenitor of many distinguished horses—thus causing him to be considered one of the best stallions of the century. During his first six years at the stud he begat stock that won no fewer than 222 races of the value of £220,343. When St. Simon was a two-year-old he ran five races and won them all, and he repeated this as a three-year-old. The Derby was instituted in 1780 and from that date until now the race has been run every year without a break, while the St. Leger, which was commenced in 1776, has also an unbroken record. The Derby is a one-and a-half-mile race, the St Leger one and three quarter miles, and the Oaks about one and a half miles The same weights are practically carried in the three races, horses carrying a few pounds more than the mares The time the Derby is run in is about 2 minutes 45 seconds, but if the ground is wet it may take as much as 3 minutes 4 seconds Blinkbonnie and Shotover covered the distance in 2 minutes 45 seconds, but Ayrshire Merry Hampton, and Blair Athol only took 2 minutes 43 seconds The winner of the Derby for 1900 was Diamond Jubilee, who also won the Two Thousand Guineas and the St Leger, and who belongs to the Prince of Wales The Duke of Westminster's Flying Fox won the Derby in 1899, and in 1896 Persimmon, also the property of the Heir Apparent, was the winner Both Diamond Jubilee and Persimmon are descendants of St Simon by Galopin, a Derby winner, out of St Angela It is an interesting fact that St Simon and Perdita II are the sire and dam of the Prince of Wales's three valuable stallions Florizel II, Persimmon, and Diamond Jubilee, who are said to be worth £120,000 Perhaps never in racing annals has the success of a sire ever surpassed that of St Simon Other horses compete with him for distinction Amongst these is The Baron, who 50 years ago was the sire of Stockwell and Rataplan, animals more valuable in the stud than on the course There is also the Duke of Westminster's Ormonde who was sold to America for £30 000 and who was the sire of Orme, an animal which is less known as a racer than as the begetter of Flying Fox, who was recently sold to France for £35,000 Add to the above facts the following—viz, that Stockwell is the sire of Doncaster, who is the sire of Bend Or, who is the sire of Ormonde, who again is the sire of Orme, by whom was begotten Flying Fox, and we have a line of famous racehorses which, like that of St Simon, goes direct back to the Darley Arabian, the father of the best blood in the racehorses of to-day On the maternal side the strain can be traced back to the Godolphin Arab, a sire who has also contributed to the production of the distinguished breed It is sometimes said of the human family that the children begotten of an elderly father are delicate Foals of ageing racehorses are considered by breeders, as a rule, not to be good winners but there are exceptions Lord Lyon, who won the Derby and St Leger, was born in 1863 He was the sire of Minting, who was born in 1883—i e, when Lord Lyon was 20 years old His previous foals, however, were of no use as winners, but Minting was an exception

What is the effect of castration upon horses from a racing point of view? The Derby is open to two year old and three year-old colts, but there is no instance of a gelding having ever won the race Ourzon who was in addition a half breed, all but succeeded in becoming the exception to this rule, but he just failed He ran second in the Derby of 1895 The more natural and the more perfect a horse is the greater is his chance of winning Entirety, therefore, counts for much even in racing

We hear a good deal in the affairs of human life of the superiority of sex, and, while there is no doubt that men occupy the higher positions in society and stand out more prominently than women, it may be that greater opportunities and advantages are afforded to the one sex than are afforded to the other Let us appeal to the experience of the Derby Girls reach maturity earlier than boys and for quick perception they are usually far ahead of boys In the racing world some experts maintain that the best mares are after all the best [illegible] equivalent to saying that mare [illegible] than the best horses that have [illegible] It is their opinion that racing is carried to greater perfection by mares than horses Probably a mare at two years old is better than a horse at that age, but it would seem as if mares deteriorate more quickly than horses and compete with them unfavourably as three year olds The Derby is an open race and there mares compete with horses They have done so and on some occasions they have won Blinkbonnie won in 1857 and Shotover in 1882 but previously to Blinkbonnie winning the race no mare had won the Derby since 1801 when to Fleanor, who was also winner of the Oaks, was awarded the palm It is only right to add that fewer mares have competed and therefore they have run against odds so far as numbers are concerned Still the fact remains that during 120 years only three mares have won the Derby It is fleetness of foot that is wanted, [illegible] what do the records show? The mares Blinkbonnie [illegible] Shotover ran the Derby in 2 minutes 45 seconds, but horses Ayrshire, Merry Hampton, and Blair Athol coursed the distance in 2 minutes 43 seconds It is only natural to [illegible] horses are like ourselves [illegible] the year we are in better [illegible] others and we do better [illegible] ng in England is in the spring and summer when mares are constantly coming into season They are consequently placed at a disadvantage as regards the Derby, which is run in the month of May September is the mare's month It is then that the St Leger is run This is a race in which mares and horses compete on equal terms, and what do its records show? Since 1776, the year in which the race was established, mares have only won 23 times out of 124 It would appear, therefore, that both in the Derby and the St Leger the greatest speed has been obtained by horses and not by mares In the breeding of racehorses it is absolutely necessary that the greatest care should be taken so as to mate sires of repute with mares that are well bred and distinguished as racers An opportunity is given to breeders to show off the racing qualities of mares at the Oaks, a race which is only for fillies and which is run two days after the Derby The winners of this race often become the dams of future winners of the Derby.

I think I have shown you that so far as racehorses are concerned the qualities that make them famous, and upon which a high money value is placed, are inherited Blood is everything, it is pedigree that commands the price and makes both horses and mares which have been the winners of the principal races so valuable for breeding when they have become old and useless for racing purposes One illustration of such a mare will suffice, and in this instance I shall take it from our own immediate neighbourhood Beeswing was born in 1833 and was the property of Mr Orde of Nunnykirk, near Morpeth She began to run when she was two years old and continued to run until she was nine years old She ran in 64 races and she won 51 times, many of the races being over two miles in length Beeswing won the Newcastle Cup and became the dam of Newminster, who won the St Leger Newminster became the sire of Hermit who won the Derby, while Hermit was the sire of St Blaise, who also won the Derby Hermit was also the sire of Thebais and Lonely, both of whom won the Oaks After 1842 Beeswing ran no more races She was simply kept at the stud and she died at the age of 21 years These facts, taken rather imperfectly from racehorses show us that it is blood or family inheritance and careful training that alone can win the Derby and that so far as the superiority of sex is concerned the evidence is in favour of the horse rather than the mare The English racehorse is the product of very close breeding in and in In the human family, to too close in breeding or consanguineous marriages is attributed such mental and physical defects in the offspring as deaf-mutism, insanity and other nervous disorders Wherever there are defects in the parents or in their family the marriage of first cousins is almost certain to be followed by an intensification of these defects in the children If close in breeding in the human family is bad, what is the result of this form of breeding carried on for so many years in the English racehorse? There are many who believe that the English racehorse of to-day is degenerating Certainly the horses are run too young, for by the time they reach four years of age many of them are practically done as racers Sprint running for man or animals is bad as the distance is covered at an excessive speed from the commencement to the finish The mode of racing itself tells upon the frame of the individual animal Add to this the cumulative effects of close in breeding and there will be much to explain the greater delicacy of constitution, the diminished resistance to cold, and the loss of staying power observed in the racehorse of to-day Breeders feel that fresh infusion of blood is necessary and that this can be obtained by the mating of an English sire, say, with a pure bred dam brought from America or Australia whose predecessors transported years ago to other soil, show a valuable pedigree which has not deteriorated in the descendants in their far off surroundings

ATAVISM.

Professor Ewart in his Penicuik experiments deals with subjects similar to those which we have been discussing and [illegible] is obvious There are uncertainties in [illegible] Galton's distinguished families [illegible] is variation Without variation life would be monotonous and there would be no development Stockbreeders take advantage of variation by perpetuating them so as to improve the breed. In the course of breeding the unexpected often happens; results occur that can only be explained by reversion, prepotency, and in breeding.

Reversion.—Members of the human family do not always bear a resemblance to their parents. The likeness is sometimes rather ancestral than parental. So far as heredity is concerned the parents, we have seen, contribute a half, the grandparents a quarter, the great-grandparents an eighth, and so on, of the total heritage of the average offspring. Composed as the ovum cells and sperm cells are of innumerable gemmules it would seem as if, during development, there occurred conditions in which protoplasmic elements of an older ancestry than the parental competed with those which were derived from the immediate parents and thus succeeded in impressing upon the individual those characters that cause the offspring to resemble, not the parents but the grandparents or even the great-grandparents. That, in a word, is an example of atavism. It is sometimes a circumstance of great value. If, for example, sporting dogs are closely inbred for three or four generations the puppies are extremely degenerated and yet in the grossly in-bred litter there is perhaps one dog who is strong and has a hardy constitution, due to what is called breeding back. He resembles, in a word, a former ancestor, so that reversion would appear to have infused fresh vigour and to have rejuvenated him owing, presumably, to ancestral units having overcome and controlled the more recently evolved and less stable units which, could they have had their own way, would have given rise to "offspring bearing all the marks of decadence that characterised the immediate ancestors."

Prepotency and in-breeding.—In the breeding of animals it is generally admitted that one of the individuals is more prepotent than the other. It is neither easy to demonstrate the fact, nor, when present, to determine the amount of prepotency. In-breeding encourages prepotency. It is because the Jews are a purer breed and an older race that when they marry with the English they are observed to be the more prepotent. In-breeding carried to excess becomes a doubtful heritage. Attempts to obtain prepotency by close in-breeding are often followed by loss of vitality and fertility. By trying to keep the blood too pure species may deteriorate. In order to maintain the vigour of a race cross-breeding becomes at times a necessity. It restores vitality. The protoplasm of animal cells has apparently assigned to it a measured lease of life and unless fresh blood is introduced to rejuvenate it the protoplasm can only give rise to a limited number of generations.

TELEGONY.

In breeding animals for sporting or other purposes the word "infection" is employed to explain the circumstance of a female who had been fertilised for the first time by a male bearing a distinctive colour and form, and who subsequently bears offspring to another male of different colour and form and yet exhibiting a distinct resemblance to the male by which the female was originally impregnated. It is owing to a belief in the occurrence of this possibility that breeders are careful of pedigree dogs and take means to prevent prize bitches being covered by dogs that are not of good breed. These men are afraid of the baser blood showing itself in future generations. It is maintained, although it is difficult to demonstrate the fact, that the same thing occurs within limits in the human female. The example of telegony taken from biology, and which appears in nearly all text-books, is Lord Morton's mare. This mare had been, in the first instance, covered by a quagga, and succeeding foals begotten by other sires showed in a descending scale stripes on the body that recalled the zebra. While Professor Ewart, in his experiments at Penicuik, obtained striping and marking of succeeding foals by different sires as in Lord Morton's mare, he explains the circumstance differently. Ewart regards the striping not so much as evidence of "infection," or "telegony," but of "reversion," for stripes, he maintains, are not unknown in Arabian horses. Belief in harking back, or "infection," is so strongly held by breeders that it must rest on some foundation. Breeders are of the opinion that in impregnation something akin to saturation of the dam's blood and nature takes place through the sire. Is it possible that there can be any absorption from the blood of the fœtus in utero by the mother? We know from experiment that the injection of diphtheritic and protective toxins into the embryos of pregnant rabbits can kill the mother in the one instance and render her immune in the other. Physiological injection is therefore a possibility, but it is difficult to see how germ-cells occupying the depths of the ovary of the female at the date of her first impregnation can have their protoplasm so impressed by the sperm cells of this sire that when subsequently impregnated by other males the progeny should bear resemblance to the original sire. There is no proof that the blood of the mother or her system can be saturated, and yet such circumstances as the following are known. In breeding Bedlington terriers it is desirable to obtain dogs with as powerful jaws as possible. A Bedlington bitch is therefore first covered by a bull-terrier dog and the mongrel litter is destroyed. Covered subsequently by a Bedlington terrier dog the litter is practically pure with the exception that the puppies have stronger jaws than they otherwise would have had, and they also show much of t[illegible] terrier. Anatomical structure and [illegible] are therefore present in the second [illegible] to the breed at all, and they could only have come from the bull-terrier. It is difficult to find examples in the human race, but Dr. Balfour of Surinam noticed among the coloured population that "if a negress had a child by a white man and afterwards fruitful intercourse with a negro, the latter offspring had generally a lighter colour than the parents." Beyond, therefore, drawing your attention to the possibility of telegony, I shall not attempt to explain it.

HEREDITY OF DISEASE.

By the term "heredity of disease" I do not mean, as in congenital syphilis, transmission of the actual disease from which a parent is suffering, but a susceptibility to disease. Among the hitherto recognised diseases might be mentioned hæmophilia, cancer, phthisis, diabetes, and the alcoholic habit. In hæmophilia there is transmitted to males, through the female who does not herself usually exhibit the disease, a peculiar defect confined probably to the walls of the small blood-vessels whereby on the occurrence of the most trivial wound—e.g., lancing the gums or the extraction of a tooth—fatal hæmorrhage may occur. The hereditary nature of this disease, or the fact that the transmission is through the female, have never been questioned. An extended genealogical tree which appears in a former paper written by myself[1] showed how, after lying dormant in the mother, the disease re appeared in her sons.

Diabetes is, in many instances, a hereditary disease. Weil, in investigating diabetes insipidus, traced 90 members of a family extending through four generations, 70 of whom were living at the time of the investigation. The disease was traced to a common ancestor, Peter Schwartz, who was born in 1772. His descendants consisted of five children, 29 grandchildren, and 56 great-grandchildren, or a total of 91 persons. Of these persons 21 were certainly diabetic and 13 were doubtfully so. Removing the doubtful cases there remained 78 persons, of whom 23 were affected with diabetes, or 30 per cent. I have at the present time under my care two brothers, aged 40 years and 43 years respectively, suffering from diabetes mellitus. In one of them the glycosuria is intermittent. The father died from diabetes and a paternal uncle is at present dying from the same disease. The maternal grandmother died from diabetes. Within the last four months I have also had under my care a father, aged 45, who is suffering from diabetes, and his daughter, aged 14 years, suffering from the same malady. The Royal Insurance Company have been good enough to send me the details of the family history of an applicant for insurance to their company. The applicant had seven brothers and one sister. The father died from diabetes, aged 65 years. One brother, aged 19 years, died from the effects of an accident. Three brothers, aged 49 years, 41 years, and 32 years respectively, died from diabetes; and one sister died from the same disease at the age of 23 years. The remaining three brothers are healthy. Facts such as these surely point to diabetes mellitus under certain circumstances being hereditarily transmitted.

When we come to deal with phthisis and cancer, the former of which is a bacillary disease, we admit that it is necessary somewhat to alter our views upon the hereditary character of these diseases. Briefly, all that can be said of pulmonary tuberculosis is that there is the accidental

---

[1] THE LANCET, Sept. 18th, 1886, p. 526.

incidence of the tubercle bacillus upon tissues that are susceptible. Experience tells us that some families are more susceptible than others to infectious diseases. Some children take every infectious disease that is going, while others, though equally exposed to infection, escape. It would seem, therefore, as if a certain habit of body was transmitted, due to some peculiarity of the idioplasm of the individual. However excellent a filter the human placenta may be it cannot prevent maternal poisons passing to the fœtus Tuberculosis itself is so very rarely transmitted directly from parent to child that at this juncture we can ignore it, nor is there any strong evidence
is transmitted and lies dormant for a p
is transmitted is the soil—an enfeebled
diminished resistance to the particular m
close intimacy that exists between an
and her infant there are doubtless opportunities given after birth for infection, but this is infection and not transmission. The soil counts for as much as the micro organism. Charrin has demonstrated experimentally that if the blood *and tissues of the body are chemically altered resistance to* pathogenic germs is diminished, while Chatin and Guinard have shown that when an animal is impregnated with excess of sugar it becomes a readier prey to the diphtheritic poison and to the infection of typhoid fever. Excess of fat also diminishes the resistance to diphtheria, whereas animals that have been exposed exclusively to proteid food resist for the longest time the diphtheritic poison. May not the lines of cellular nutrition which are laid down in the fœtus in
the explanation of suscepti-

ccuracy the medical history of any human family, for where there are mental and physical defects there is rather a desire to conceal than to publish the facts. The records of insurance companies, however, to some extent remedy this deficiency. Before examining a life for insurance the details of the family history have generally been supplied to the offices. Within the last 50 years the span of human life has distinctly lengthened. In England and Wales during the period from 1841 to 1850 the death rate in males of all ages was 23 1 per 1000. During the years from 1886 to 1889 the rate was 20 per 1000, while among females the rates were 21 6 and 17 8 per 1000 respectively, showing, therefore, a distinct gain. Opposed to these facts must be placed the number of births The birth rate of this country during 1842 equalled 32 6 per 1,000,000 of the population, while in the period from 1886 to 1890 it equalled 31 4—a fall in the birth-rate which, if it continues, may jeopardise the future of England just as at the present time it is the cause of anxiety in France.

Pulmonary phthisis has for long been regarded as hereditary. Where there is a family history of phthisis insurance companies may accept the life, if the applicant is under 30 years of age and physically strong, but they will load it by adding a few years to it, or if several members of the family have died from phthisis they will refuse the life altogether. Experience has taught them that members of a family, some of whom have already succumbed to phthisis, are much more liable to the disease than members of other families which have no such
that has come over medical o
tariness of phthisis, to fulle
character, to improvement of
and to the fact that the death rate from this disease is diminishing, insurance companies are disposed, according to the extent of the taint in the family, to offer less stringent terms than formerly. During the years from 1858 to 1860 the number of people in England and Wales who died from phthisis was on the yearly average 2565 per 1,000,000 During the period from 1871 to 1875 the average number was 2218 Between the years 1886 and 1890 the death-rate from this cause was 1635, in 1891 it was 1599, and in 1892 it stood at only 1468 Within these years there has been a fall in the mortality-rate of phthisis of 42 per cent The diminution of the death-rate may be consequent upon our better knowledge of the infectious nature of the malady and improvement in the housing of the working classes, or it may possibly be due to reversion, as in the case of in-bred animals, to a healthier stock. Notwithstanding Weismann's theory that acquired characters are not transmitted, and that the germ-plasm alone is transmitted, there is yet implanted in the nucleus of
e cannot but be
that surrounds
it, and hence while Weismann's theory explains much in heredity there are still conditions that are not explained by it. Experience and statistics alone can settle the question of family phthisis. Because the death-rate from phthisis is diminishing that is no proof that the disease is not hereditary. All that this circumstance shows is that there are fewer cases of acquired as well as of inherited phthisis, and that improved vital resistance on the part of the individual is to some extent overcoming the hereditary influence.

The Mutual Life Insurance Company of New York has

and the same diseases that affect youth carry off people in old age. Tuberculosis caused 5585 deaths, and with the exception of 133
were affected in all. Dividing
those under 45 years *of age*,
60 years of age, and (3) those above 60 years of age—it is observed that the mortality-rate of tuberculosis is highest at the early ages and diminishes with advancing years, although it is still

under 45) shows 59 2 per cent., the second age-period 28 94 per cent., and the third age-period 11·85 per cent, while taking the total deaths from all causes, tuberculosis caused 24·27 per cent., 10 88 per cent, and 4 03 per cent. of the deaths in the respective periods.

TABLE I.—*Showing the Mortality from Tuberculous Diseases for Various Age periods (Mutual Life Insurance Company of New York).*

Age-periods.	Number of deaths.	Percentage	Percentage of total deaths from all causes
Under 45 years . .	3307	59·21	24·27
From 45 to 60 years	1616	28·94	10·88
Above 60 years . ..	662	11·85	4·03
Total	5585	—	—

Table I. shows that the largest percentage of deaths from phthisis occurred under 45 years of age, and that no period of life was free from it.

TABLE II.—*Showing the Mortality from Tuberculous Diseases in Non consumptive and Consumptive Families respectively (Mutual Life Insurance Company of New York).*

Age at death.	Deaths in non-consumptive families.			Deaths in consumptive families		
	From all causes.	From tuberculosis.	Percentage of deaths from tuberculosis.	From all causes.	From tuberculosis.	Percentage of deaths from tuberculosis.
To 29 years	106	38	35·8	60	31	51·6
From 30 to 39 years	372	93	26 3	194	77	39 6
„ 40 to 49 „	506	100	17 6	284	70	24 6
„ 50 to 59 „	724	49	6 7	489	77	15·7
„ 60 to 69 „ . „	613	36	5 8	569	47	8·2
„ 70 to 79 „	325	12	3 7	358	8	2 2

Table II. shows that the greatest number of deaths from phthisis occurs under 30 years of age, both in families that have a history of the disease, and in those that are non-consumptive, and that it is larger in the "tainted" than in the "non-tainted" section for every decennial period of life to extreme old age. The taint, therefore, would seem to last

advancing years, owing to the fact that other diseases come upon the scene. It is in the early years of manhood that phthisis claims the largest number of victims, for after middle age degenerative diseases of the circulatory and nervous systems make their appearance and cause it to assume a less conspicuous position. The age of 35 years, in the experience of the Scottish Widows Fund, is that in which the largest number of deaths occurs from phthisis. From the tables drawn out by the Mutual Life Insurance Company of New York it appears that a family history of phthisis indicates (1) a liability to the disease on the part of an applicant for life insurance, and (2) that the amount of this increased liability may be estimated at 30 per cent., an estimate that holds good certainly until the age of 50 years is reached. Naturally, where there is a history of two or more tuberculous persons in a family this circumstance is of more ominous importance than where there is the record of only a single case, and the death of a parent would carry more weight than that of a brother or a sister, especially up to the age of 40 years. There is a belief that of the two parents the mother who is consumptive and in whose family there are records of this disease is more likely to transmit a liability to phthisis than the father. The statistics of the Mutual Life Insurance Company of New York, however, rather point the other way and show that the percentage liability to phthisis between 20 and 29 years of age is 43 3 when the father has died from phthisis, and 36·5 when the mother was the subject of the malady. Another point sometimes raised is whether the tendency to phthisis is not more marked between brothers and sisters than between parents and children.

TABLE III.—*Showing the Proportionate Mortality from Tuberculosis among those with tainted Record and arranged according to the Degree of Taint and the Age at Insurance.*

Number of members of family affected	Total.	Age at insurance			
		20 to 29 years	30 to 39 years.	40 to 49 years.	50 years and upwards
	Per centage	Per-centage	Per-centage.	Per-centage.	Per-centage
Both parents .	14 3	—	—	50 0	—
Father	20 7	43 3	16 1	10 4	9 6
Mother ..	15 5	36 5	17 1	7 5	4·6
Parent and brother or sister	11 0	18·2	21 4	5·5	—
One brother or sister	14 3	34·1	20·6	10 2	4 3
Two or more brothers or sisters	19 4	62 5	42 4	7 5	7 5
Tuberculosis percentage ..	12·7	28 5	13·3	6 8	4 6

Where there is a history of tuberculosis in both parents insurance companies will hardly accept the life. The statistics of double inheritance in the preceding table refer to such a small number of cases that they scarcely give us complete information upon this part of the subject. Besides, where there is a history of phthisis in a family it does not necessarily follow that the sons and daughters shall die from the disease. All that can be said is, that there will be in them a greater predisposition to phthisis. Since, therefore, individuals of a tainted family may completely escape phthisis, this circumstance suggests that conditions are in operation to neutralise this hereditary tendency. Improved external surroundings, better ventilated homes and workshops, less dusty occupations, and improvement in the physique of the individual as shown by greater muscular vigour, increased weight of body and chest measurement, render the individual less liable to phthisis. All "consumptives," as the name naturally suggests, are below the normal weight. It is known that "the highest proportion of consumption mortality, and the highest proportion of underweights are found before middle age; the least percentage of consumption mortality and the highest proportion of overweights after middle age." In persons with no history of phthisis in the family there are twice as many deaths among those below than above the average weight, while in tainted families the percentage is greater—circumstances which show that poor physique and enfeebled nutrition play some part in the causation of the disease. In the experience of the Scottish Widows Fund 80 per cent. of the sufferers from phthisis fell short of the average of weight to height. Light weight, and especially losing weight, are precursors of phthisis. Robust bodily development is therefore not without a favourable influence, and yet it does not prevent phthisis, for I have seen some of the strongest athletes with splendid physical frames, sons of a tainted family, succumb one after another to the inherited malady. Nor, on the other hand, does robust physical development, even in the absence of family taint, ensure against the danger of phthisis. All are liable to phthisis but the liability is shared unequally. While, therefore, we admit that the family history has a value which cannot be ignored, personal development, station in life, occupation, and surroundings are circumstances that play a part in the causation of disease as great as, if not greater than, inheritance. Dr Claud Muirhead,[2] medical referee to the Scottish Widows Fund, states that 15 per cent. of their applicants for admission show a family record of phthisis, and that in his experience undoubted phthisis is more frequently transmitted by the mother than by the father, the ratio being 6·29 per cent. on the side of the father as against 8·97 per cent. on that of the mother. The experience of the Scottish Widows Fund in regard to phthisis is, generally speaking, much more favourable than that of the American office. It shows that the tendency for phthisical parents to beget phthisical children is small, the difference between the two classes of parents being only 1 per cent., the number being 8 per cent. for consumptives and 7 per cent. for non-consumptives. The subjoined table shows that where lives are selected *after* medical examination the death-rate from phthisis is distinctly lower than that of the community so far as Scotland, at any rate, is concerned, but not of people living in the country districts after 30 years of age.

TABLE IV.[3]—*Percentage of Deaths from Consumption on the Total Mortality from all Causes for each Decennial Period of Adult Life (Scottish Widows Fund)*

Age.	Scottish Widows Fund.	Mutual Life Assurance Company.	New York Assurance Company.	Scotland.	Ten Scotch counties

All ages above 20	9 51	19 74	29 38	13 60	11·75

The Royal Life Insurance Company has, like the Scottish Widows Fund, been good enough to favour me with their experience of tuberculosis. Taking 188 of their deaths from this disease I find that the greatest number occurred from the fiftieth to the sixtieth year of age, that in 25 cases a parent, a brother, or a sister had died from phthisis, that in 19 one or more of the grandparents had died early (many of them presumably from phthisis), and that in at least nine of these there was a history of a parent, or brother, or sister having died from tuberculosis.

In spite of all that has been said and published by insurance offices there are still many who do not believe in the inheritance of phthisis. Personally I have no doubt as to the transmission of a susceptibility to phthisis, but the influence of this is much less than we have hitherto believed, and apparently it is in these latter years a diminishing factor. Admitting for good or ill all the influence of external surroundings, it is impossible to ignore the history of tuberculous disease in the family that is given by patients who came to the Newcastle on-Tyne Infirmary and to our consulting-rooms. Dr. Reginald E. Thompson[4] tabulated all the cases admitted into the Brompton Hospital for Consumption from 1855 to 1880—i.e., a quarter of a century. The history of each case was carefully recorded by the clinical assistants and the diagnosis made by the physicians, care being taken to exclude such errors as the possibility of infection from one member of the family to another. Dr. Thompson's experience confirms what has already been said. He shows, too, that where there is a family history of phthisis the members of that family who *become phthisical do so at an earlier age than those of an untainted family* who acquire the disease; also that where there is a history of both parents having been tuberculous there is not only a greater liability to the disease but that it develops at a still earlier age than when there is only a single inheritance. Out of 3000 cases at Brompton Hospital Dr. Thompson found that 36 per cent. of the males gave a family history of phthisis and 58 per cent. of the females the same. In 80 cases of well-marked family phthisis he found a history of paternal inheritance in 24 instances and maternal inheritance in 30 cases, double heredity in 14 cases, and atavism in 12 cases. Among these 80 families 385 children were born, of whom 203 were males and 182 females. In them phthisis appeared in 98 males and 96 females, there died in childhood 21 males and 16 females, and there remained apparently healthy 84 males and 70 females. In other words, 194 members of these tainted families, or one half, died from phthisis, 37 of the deaths occurring in childhood. It is Dr. *Thompson's opinion that the effect of* paternal inheritance upon males is to cause phthisis to appear at an earlier age than in the parent and to reduce the constitutional resistance of the individual to the disease, while upon the females it also causes an earlier manifestation of the disease, but if anything increases their resistance to it. The influence of tuberculous mothers, on the other hand, upon males is to increase the tendency to rather copious bleedings from the lungs, a circumstance not so noticeable in females.

[4] Family Phthisis.

I have dwelt upon the evil effects of "in-breeding" in animals. If these are bad in the case of animals how very much aggravated must they be in the human race when there is a family history of phthisis. On humanitarian grounds alone consumptives *should not marry. Marriages, however,* are not regulated by reason but by sentiment, and even when circumstances are made clear to one of the contracting parties, an expression of optimism usually prevails before which pathology generally has to bow.

We have seen that there is an individual and family susceptibility to phthisis. There is also a racial susceptibility and no one doubts that the characters of race are inherited. Over a period of six years ending in May, 1890, it was estimated that in every 100,000 of the population of New York phthisis claimed on an average 238 48 per annum of the white native population, 483 83 of the foreign white population, and 774 21 of the coloured population. Negroes and the offspring resulting from the union of the white and coloured races in America are extremely susceptible to phthisis, *and yet while the negroes* exhibit this excessive liability to the disease the Jews are wonderfully exempt from it. Out of every 1000 of the total deaths of the whole of the United States, pulmonary consumption carried off in 1880 108 79 of the general population but only 36·57 of Jews. This freedom of the Jews *from* consumption has *for long* attracted attention. It can scarcely be said that their homes are more sanitary than those of Christians or that they are more given to ventilating them. As a class they are more abstemious and their food is better prepared and they are the *more vigorous race.* That over-populated districts are unhealthy requires no demonstration. Dr. J. B. Russell of Glasgow found that where the death-rate was greatest the cubic space was smallest. In 100,000 of the population the death-rates from diseases of the lungs, including phthisis, were in one-roomed or two roomed houses 985, in three-roomed or four-roomed houses 689, *and in five-roomed houses* and upwards 328. Where overcrowding exists there is a greater tendency to tuberculous disease simply on the ground of contagion. It is not that the tuberculous patient gives off in his breath bacilli into the atmosphere, but that the sputum contains the microbes and *as* the expectoration heedlessly spat upon the floor dries and is ground into dust this rises into the atmosphere, is inhaled, and so the disease spreads. Each individual becomes thus a centre of infection to others.

We have *seen* that not only in the medical profession but in the public mind and in insurance offices there is a belief that pulmonary phthisis is hereditary. Careful sifting of all the facts shows that the extent of the inheritance has been exaggerated.

Without carrying the remainder of this inquiry much further I shall only say a few words on the question of the hereditariness of cancer. The mortality records of the Mutual Life Insurance Company of New York deal with 1882 deaths from cancer. The age period in which the largest number of deaths from cancer occurred is from 55 to 60 years. Statistics, both in England and in America, show that the rate of mortality from pulmonary phthisis is decreasing while the deaths from cancer are notably on the increase. It may be that cases are more carefully diagnosed now than formerly, but apart from this probability, there is a very strong feeling in the medical profession that *cancer is more prevalent than it was.* Taking the cancer returns of the American insurance office I find that while in 1879 the percentage of deaths from cancer between the ages of 50 and 70 years was 4·23, in 1889 it was 6 22, and in 1898, 7·59. In support of the opinion that cancer is increasing I would also draw attention to the statistics of the Scottish Widows Fund kindly placed at my disposal by Dr. Claud Muirhead, principal medical adviser to that society. From 1815 to 1845 the deaths from cancer were 0 93 per cent. of the whole number. From 1845 to 1852, they were 0 72 per cent., from 1852 to 1859 2·87 per cent., from 1859 to 1867 3 0 per cent., from 1867 to 1873 4·56 per cent., from 1873 to 1880 4·34 per cent., and from 1880 to 1887 5·23 per cent. *Allowing for greater accuracy in the returns* Dr. Claud Muirhead admits that "the number of deaths from this cause has increased enormously, the number being more than 40 times greater than in the previous 37 years." Females die from cancer in a proportion double to that of males, their mean age at death being 62 69 years, as against 60 43 years of males. In regard to the hereditariness of cancer the statistics of the Scottish Widows Fund show that only in *9 5* per cent. was there *a history of malignant* disease in the parents. In 11 of the cases the disease was transmitted through the father, in 14 cases through the *mother*, and in one case a brother was similarly affected. The hereditary transmission of cancer is considered to be *not so great* as that of phthisis, a fact that must be comforting to many people who have lost near relatives from cancer.

Summing up the subject, as to what is inherited from our parents, I would say that from a physiological point of view there is considerable evidence to show that mental, not less than physical, qualities are transmitted, that pathologically such a disease as hæmophilia is inherited, and that where there is a family history of phthisis and cancer there is, especially as regards phthisis, a greater liability to the disease than where a family shows no such record. I believe that the influence of inheritance, however, has been exaggerated. Tuberculous disease is inherited, but only in the same sense as other diseases that are due to microbes. It is in the form of an enfeebled resistance on the part of the *tissues*. Pulmonary phthisis seems to exhibit a kind of inheritance that *is particularly its own*, but on scrutiny this is found to be largely due to the domestic character of the malady which is encouraged by our home life, insanitary dwellings, overcrowding of the poorer working classes, infection, Britain's changeable climate, dusty occupations, and ill-assorted marriages.

TWO CASES OF ACUTE HÆMORRHAGIC PANCREATITIS.

BY J. H. BRYANT, M D , M R C.P. LOND.,[1]
ASSISTANT PHYSICIAN AND DEMONSTRATOR OF MORBID ANATOMY AT GUY'S HOSPITAL.

I PUBLISH these two cases as they present some curious features which I have not been able to find recorded before. If perchance I have missed any case in which similar changes have been noted I take this opportunity of apologising to the author or authors for claiming them as new. In *Case 1* when performing the necropsy I found marked fat necrosis of the mediastinal and pericardial fat and in both cases at the time of the operation the peritoneal cavity was found to be distended with large quantities of bile-stained *serous fluid*.

CASE 1.—The patient, a bandmaster, aged 38 years, was admitted into Luke Ward at Guy's Hospital on May 31st, 1899, under the care of Mr. L. A. Dunn, for excruciating general biliary pigmentation, although the urine contained a large amount of bile, a condition which was noted before death. The liver weighed 51 ounces. A depressed, wedge-shaped, dull yellowish-looking area was found at the edge of the left lobe extending upwards for about half an inch and being about a quarter of an inch in thickness. In appearance it resembled an infarct more than anything else. The kidneys weighed eight ounces. The left kidney was normal. The perinephric fat surrounding the right kidney was bile-stained and showed numerous opaque, milk-white, and orange-yellow spots and patches of fat necrosis. The spleen weighed three and a half ounces. It was quite healthy. The suprarenals were normal

Sections from different parts of the pancreas were examined under the microscope. It was found that the pancreas was not involved throughout. All the sections examined showed areas where the acini and their cells appeared to be quite normal. Irregular-shaped areas were also seen, the central parts of which appeared to be made up of a granular débris, no outline at all of the acini or their epithelial cells being visible. Dotted about in this granular débris were a number of polymorpho-nuclear leucocytes. There were also several patches where this granular débris was stained a bright golden colour (? bilirubin). In places effusion of blood could be seen into the inter-lobular tissue. The blood-vessels generally were distended with blood and some of the smaller ones were filled with thrombi partially organised. At the periphery of the necrosed areas the outline of the acini and their cells could be seen, but the protoplasm of the cells had a very granular appearance and their nuclei were not stained. Some of these cells were stained a bright golden colour and contained granules of this pigment. Outside these the cells were faintly stained and outside these again the acini appeared to be normal. There was undoubted parenchymatous inflammation, necrosis of the glandular tissue, pigmentation, and blood effusion and infiltration. Numerous patches of fat necrosis were seen also in the interlobular connective tissues. Sections stained with carbol thionin blue and examined with a $\frac{1}{12}$th oil immersion did not show the presence of micro-organisms. Cultures were taken and a pure growth of the bacillus coli communis was obtained.

Remarks.—Case 1 was not diagnosed during life. The history of previous attacks of abdominal pain and indigestion spreading over several years, and the acute onset of severe abdominal pain after a late meal of pigeon-pie, seemed to point to perforating gastric ulcer as the most likely explanation of the patient's condition when he was seen on his admission into the hospital. A satisfactory elucidation, however, of the cause of these attacks of pain was found at the necropsy in the gall-bladder, which contained several calculi. A small calculus was also found in the other case, lying in a fold of mucous membrane in the common duct close to the opening of the cystic duct. This association of gall-stones with acute hæmorrhagic pancreatitis is far from being uncommon. If the calculi are formed as a result of changes in the ducts and gall-bladder produced by an invasion of the bacillus coli communis, and as in nearly all of the cases of pancreatitis which have been examined bacteriologically the bacillus coli communis has been found, the invasion of the organ by this organism may have been the cause of this disease, for if the bacillus has ascended the bile duct, the cystic duct, and the hepatic duct it might at the same time just as easily have invaded the pancreas by means of the duct of Wirsung. The diagnosis was cleared up by the operation, fat necrosis being found. The bile-stained peritoneal fluid I shall refer to when discussing Case 2

The chief point of interest in Case 1 was the finding of fat necrosis outside the peritoneal cavity. No mention of such a possibility is mentioned either in Osler's, Taylor's, or Allbutt's "System of Medicine." Osler[1] writes: "A point of interest is the relation of fat necrosis to pancreatic disease. The areas are found in the interlobular pancreatic tissue, in the mesentery, in the omentum, and in the abdominal fatty tissue generally." Fitz, in his article in Clifford Allbutt's "System of Medicine," chiefly draws attention to sub-peritoneal fat necrosis.

A good deal of experimental work has been done on fat necrosis, but I have not been able to find any note of it as having occurred outside the peritoneal cavity. Flexner[2] and Williams[3] have published the results of their work on the pathology of this curious change in the fat and they both give important summaries of the work of other pathologists. The first pathologist who directed attention to fat necrosis was Balser[4] in 1882; he found it either within the inter-acinous tissues of the pancreas or in the adjacent and distant fat. Langerhans[5] injected the sterilised pulp of fresh pancreas into the peritoneal tissues of rabbits and inflammation resulted with evidence of fat necrosis. He, however, only had one successful experiment out of 12. He satisfied himself that a decomposition of the fat molecule occurred with liberation of the fatty acids and considered that it was due to the action of the fat-splitting ferment. Dettner[6] experimented with pure trypsin which produced a sero-hæmorrhagic effusion in the peritoneal cavity but no fat necrosis. Hildebrand[7] suggested that the hæmorrhage in acute hæmorrhagic pancreatitis was due to trypsin and that the fat necrosis was caused by the action of the fat-splitting ferment. Hlava[8] produced hæmorrhagic pancreatitis and fat necrosis by injecting Klebs-Löffler bacilli into the pancreas after a laparotomy. Rosenbach and Jung[9] experimented with trypsin and with portions of pancreas which they introduced into the abdominal cavities of rabbits. They obtained fat necrosis with pieces of pancreas once out of four times. Flexner's conclusions are as follows:—1. In peritoneal fat necrosis the fat-splitting ferment is demonstrable at certain stages of the pathological process. 2. It is present in greatest amount in the early stages and may disappear in the later ones when the healing is well advanced. 3. Although it cannot be affirmed that steapsin is the direct cause of the necrosis of tissue such an assumption is rendered highly probable by its constant occurrence in the diseased areas, its absence from the healthy fat, and the nature of the pathological changes. 4. The escape of the pancreatic secretion into the peri-pancreatic and pancreatic tissues is the origin of the necrosis and this escape is facilitated chiefly by lesions of the pancreas itself, but also by disturbances in its circulation. Williams concluded that there was some substance in the pancreatic tissue, probably the fat-splitting ferment, which had the power of producing changes in fat similar to those found in fat necrosis.

It will be seen from the above that experimental evidence goes to show that fat necrosis is caused by an escape of the pancreatic secretion into the peri-pancreatic and pancreatic tissues. The changes in the mediastinal and pericardial fat could not be explained exactly in this way, as there was certainly no direct communication between the peritoneal cavity and the pericardial sac. If fat necrosis is due to the action of the fat-splitting ferment of the pancreatic secretion it must have been carried to the pericardial and mediastinal fat by the blood, or by the lymphatic vessels, or by both. It is a well-known fact that a pericarditis or pleurisy may proceed from a peritonitis and that the channel of infection is along the blood-vessels or lymphatics, and I see no reason why the pancreatic secretion should not be carried in a similar manner. The reddish areas of hæmorrhage which were noted in the fat of the mesentery, which were similar in size and form to the areas of fat necrosis, suggested that the factor causing the fat necrosis was carried in the blood-vessels.

In Case 2 the previous history of abdominal pain and indigestion and the acute onset with pain suggested perforating gastric ulcer as the most likely diagnosis to explain his symptoms and condition. The fulness in the upper part of the abdomen, the tenderness situated midway between the umbilicus and ensiform cartilage, and the curious area of dulness made me seriously consider the possibility of acute hæmorrhagic pancreatitis being the disease from which the patient was suffering. The previous history of jaundice and abdominal pain I did not consider to be against this view, as a few months before I had seen a case of acute hæmorrhagic pancreatitis giving a similar history (Case 1). At the necropsy on this case gall-stones were found and fully accounted for the previous attack of abdominal pain and jaundice.

The most striking point of interest about Case 2 and the one I wish to draw particular attention to was the large collection of clear, bile-stained, serous, sterile fluid found in the peritoneal cavity at the time of the operation. It puzzled us a good deal and many suggestions were made to explain its presence. No fat necrosis was found and the pancreas did not appear to be enlarged, so that the diagnosis of acute hæmorrhagic pancreatitis was given up. It was suggested that possibly the bile stained fluid might be accounted for by a perforating ulcer of the duodenum, but against this view was the absence of peritonitis, the clear character of the fluid, which proved also to be sterile, and the fact that the duodenum was carefully examined and found to be intact. The gall-bladder at the time of the operation was shown to be full of bile and intact, so that a perforation or rupture of this organ was excluded. The cystic duct was also normal but the bile ducts and the hepatic ducts could not be satisfactorily examined. We thought that possibly one of the ducts had ruptured and that the previous attack of pain and jaundice suggested a gall-stone as being the most probable cause of the trouble. At the necropsy a biliary calculus was found, but it was small and was not obstructing the flow of bile The tissues in the neighbourhood of the bile-passages and pancreas had a swollen and sodden [illegible]

bile [illegible] I thought that the inflammatory and sodden condition of the tissues and ducts had allowed of an escape of bile into the peritoneal cavity by means of either the lymphatics or blood-vessels, or [illegible] and the urine both c[illegible] there was no gener[illegible] point in favour of a [illegible]tity of bile-stained serous fluid was also found in the peritoneal cavity of Case 1 at the time of the operation, and at the necropsy the tissues in the neighbourhood of the bile passages were stained with bile Another point of interest in Case 2 was the marked pigmentation of some of the cells and of the débris in the affected areas.

ON THE INFLUENCE OF FATIGUE ON THE MINUTE STRUCTURE OF THE KIDNEY AND LIVER:

PRELIMINARY ACCOUNT.

BY DR. GUIDO GUERRINI.

IN a fatigued organism *there circulates, as is known*, a very large quantity of particular substances which, when collected and spread through all the system, produce a certain condition the manifestations of which, perhaps, constitute in great part the symptomatology of fatigue. *Now, given the presence in the circulation of such substances* and given, on the other hand, the great ease with which the cells of the organ react in their minute structure to such conditions, it is not difficult to deduct that in fatigue also the organs will show some change in their cellules It is *just this hypothesis that I have sought to verify.* The minute modifications of structure which I saw in the nerve-cells of the cerebral and cerebellar cortex have been already published, and the minute modifications of structure which I saw in the nerve cells of the spinal marrow will soon be published, but in the meantime in this preliminary note I give *the results which I have already obtained as regards the* kidney and liver—two organs which from the nature of their functions must certainly be affected by the presence in the circulation of the products of muscular exchange during fatigue. The technical part of the experiments was the same as that which I used for the study of the nervous system. I made several dogs run within an *apparatus* resembling that used by Grandis for the study of the influence of work, fasting, and temperature on the production of carbonic acid and the diminution in weight of the organism until they evinced symptoms of very evident fatigue. Afterwards I killed the animals with numerous special precautions and sought for the alterations in the minute structure of the kidney and liver caused by the excessive work. All the experiments were begun only after a certain time (the same for all the animals) after the last meal. The results of my experiments are the following.

In the kidney.—The grosser modifications of structure are in the cells of the convoluted tubules and of the ascending part of the loop of Henle. The corpuscles of Malpighi and the collecting tubes are nearly always normal. In the affected cells the modifications of structure are, naturally, in relation with the degree of fatigue undergone by the animal. The more fatigued the dog was the more profoundly altered were the cells. In animals already much fatigued the following appearances may be observed. The protoplasma loses its usual aspect and becomes homogeneous and granular. It appears that the cellular body enlarges, sometimes little, sometimes so much that in a transverse section all the openings of the canals seem to be closed by the swollen cells. The edge between the cells becomes uncertain and sometimes disappears altogether. In animals still more fatigued the minute modifications of the cells of the convoluted tubules are, as I have said, much greater. It is seen, in fact, that the borders of the cells which surround the opening of the canals fray out and break and that the cellular protoplasm shows here and there rarefied points, vacuoles and cracks, and finally crumbles away into a fine detritus which collects in the opening of the tubules In the midst of [illegible] sometimes [illegible] nuclei. Thi[illegible] certain number of cells, but sometimes it is seen only in a group of a few diseased cells which are in the midst of several normal ones.

In the liver.—The minute modifications of structure of the liver cells are much less than are those of the kidney cells, and they appear conspicuously only in the liver of those dogs in which the modifications of structure are the greatest. They are as follows. From the beginning all the cellular protoplasm appears homogeneous, cloudy, and granular. The cellular body enlarges and the edge between the cells becomes uncertain and sometimes disappears altogether. Sometimes the little biliary canals are evidently compressed, whereupon *the protoplasma of the liver cells* appears rarefied, full of knots, spongy, and very dark from biliary pigment

These are, in short, the results of my researches on the influence of fatigue on the minute structure of the kidney and liver. I will systematically continue the researches on the other organs.

A SERIES OF ELEVEN OPERATIONS FOR PERFORATED GASTRIC ULCER.

BY G. H. HUME, D.C.L. DURH., M.D., F.R.C.S. EDIN.,
SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

THE 11 cases in the accompanying table have been operated upon during the past seven years and form a complete list of all the cases of acute perforation and gastric ulcer on which I have operated. The results agree in the main with the most recently published statistics and illustrate both the recent improvement in results and the dependence of this improvement on earlier opportunity of operating. *A few remarks suggested by the cases may be* arranged under the following heads.

Diagnosis—In only one of the cases (Case 9) was there doubt when first seen as to the occurrence of perforation. The patient was seen in the night and had quite recovered from the collapse which marked the beginning of the illness. She was left till morning when the signs of commencing peritonitis were too evident to admit of further delay and she was operated on with good result In another case (Case 3) there was doubt as to the origin of the general peritonitis which was fully developed. There was a history of a previous attack of peritonitis; the present illness was *said to have begun* with *pain* and tension in the right iliac region and it was uncertain which *of* the two—a perforated appendix or perforated gastric ulcer—was the source of infection. An exploration of the region of the appendix was first made with negative result; then the epigastric region was opened and the perforation *was found.* As a rule it is not difficult to make an early diagnosis The past history of stomach trouble, general biliary pigmentation, although the urine contained a large amount of bile, a condition which was noted before death. The liver weighed 51 ounces. A depressed, wedge-shaped, dull yellowish-looking area was found at the edge of the left lobe extending upwards for about half an inch and being about a quarter of an inch in thickness. In appearance it resembled an infarct more than anything else. The kidneys weighed eight ounces. The left kidney was normal. The perinephric fat surrounding the right kidney was bile-stained and showed numerous opaque, milk-white, and orange-yellow spots and patches of fat necrosis. The spleen weighed three and a half ounces. It was quite healthy. The suprarenals were normal

Sections from different parts of the pancreas were examined under the microscope. It was found that the pancreas was not involved throughout. All the sections examined showed areas where the acini and their cells appeared to be quite normal. Irregular-shaped areas were also seen, the central parts of which appeared to be made up of a granular débris, no outline at all of the acini or their epithelial cells being visible. Dotted about in this granular débris were a number of polymorpho-nuclear leucocytes. There were also several patches where this granular débris was stained a bright golden colour (? bilirubin). In places effusion of blood could be seen into the inter-lobular tissue. The blood-vessels generally were distended with blood and some of the smaller ones were filled with thrombi partially organised. At the periphery of the necrosed areas the outline of the acini and their cells could be seen, but the protoplasm of the cells had a very granular appearance and their nuclei were not stained. Some of these cells were stained a bright golden colour and contained granules of this pigment. Outside these the cells were faintly stained and outside these again the acini appeared to be normal. There was undoubted parenchymatous inflammation, necrosis of the glandular tissue, pigmentation, and blood effusion and infiltration. Numerous patches of fat necrosis were seen also in the interlobular connective tissues. Sections stained with carbol thionin blue and examined with a $\frac{1}{12}$th oil immersion did not show the presence of micro-organisms. Cultures were taken and a pure growth of the bacillus coli communis was obtained.

Remarks.—Case 1 was not diagnosed during life. The history of previous attacks of abdominal pain and indigestion spreading over several years, and the acute onset of severe abdominal pain after a late meal of pigeon-pie, seemed to point to perforating gastric ulcer as the most likely explanation of the patient's condition when he was seen on his admission into the hospital. A satisfactory elucidation, however, of the cause of these attacks of pain was found at the necropsy in the gall-bladder, which contained several calculi. A small calculus was also found in the other case, lying in a fold of mucous membrane in the common duct close to the opening of the cystic duct. This association of gall-stones with acute hæmorrhagic pancreatitis is far from being uncommon. If the calculi are formed as a result of changes in the ducts and gall-bladder produced by an invasion of the bacillus coli communis, and as in nearly all of the cases of pancreatitis which have been examined bacteriologically the bacillus coli communis has been found, the invasion of the organ by this organism may have been the cause of this disease, for if the bacillus has ascended the bile duct, the cystic duct, and the hepatic duct it might at the same time just as easily have invaded the pancreas by means of the duct of Wirsung. The diagnosis was cleared up by the operation, fat necrosis being found. The bile-stained peritoneal fluid I shall refer to when discussing Case 2.

The chief point of interest in Case 1 was the finding of fat necrosis outside the peritoneal cavity. No mention of such a possibility is mentioned either in Osler's, Taylor's, or Allbutt's "System of Medicine." Osler[1] writes: "A point of interest is the relation of fat necrosis to pancreatic disease. The areas are found in the interlobular pancreatic tissue, in the mesentery, in the omentum, and in the abdominal fatty tissue generally." Fitz, in his article in Clifford Allbutt's "System of Medicine," chiefly draws attention to sub-peritoneal fat necrosis.

A good deal of experimental work has been done on fat necrosis, but I have not been able to find any note of it as having occurred outside the peritoneal cavity. Flexner[2] and Williams[3] have published the results of their work on the pathology of this curious change in the fat and they both give important summaries of the work of other pathologists. The first pathologist who directed attention to fat necrosis was Balser[4] in 1882; he found it either within the inter-acinous tissues of the pancreas or in the adjacent and distant fat. Langerhans[5] injected the sterilised pulp of fresh pancreas into the peritoneal tissues of rabbits and inflammation resulted with evidence of fat necrosis. He, however, only had one successful experiment out of 12. He satisfied himself that a decomposition of the fat molecule occurred with liberation of the fatty acids and considered that it was due to the action of the fat-splitting ferment. Dettner[6] experimented with pure trypsin which produced a sero-hæmorrhagic effusion in the peritoneal cavity but no fat necrosis. Hildebrand[7] suggested that the hæmorrhage in acute hæmorrhagic pancreatitis was due to trypsin and that the fat necrosis was caused by the action of the fat-splitting ferment. Hlava[8] produced hæmorrhagic pancreatitis and fat necrosis by injecting Klebs-Löffler bacilli into the pancreas after a laparotomy. Rosenbach and Jung[9] experimented with trypsin and with portions of pancreas which they introduced into the abdominal cavities of rabbits. They obtained fat necrosis with pieces of pancreas once out of four times. Flexner's conclusions are as follows:—1. In peritoneal fat necrosis the fat-splitting ferment is demonstrable at certain stages of the pathological process. 2. It is present in greatest amount in the early stages and may disappear in the later ones when the healing is well advanced. 3. Although it cannot be affirmed that steapsin is the direct cause of the necrosis of tissue such an assumption is rendered highly probable by its constant occurrence in the diseased areas, its absence from the healthy fat, and the nature of the pathological changes. 4. The escape of the pancreatic secretion into the peri-pancreatic and pancreatic tissues is the origin of the necrosis and this escape is facilitated chiefly by lesions of the pancreas itself, but also by disturbances in its circulation. Williams concluded that there was some substance in the pancreatic tissue, probably the fat-splitting ferment, which had the power of producing changes in fat similar to those found in fat necrosis.

It will be seen from the above that experimental evidence goes to show that fat necrosis is caused by an escape of the pancreatic secretion into the peri-pancreatic and pancreatic tissues. The changes in the mediastinal and pericardial fat could not be explained exactly in this way, as there was certainly no direct communication between the peritoneal cavity and the pericardial sac. If fat necrosis is due to the action of the fat-splitting ferment of the pancreatic secretion it must have been carried to the pericardial and mediastinal fat by the blood, or by the lymphatic vessels, or by both. It is a well-known fact that a pericarditis or pleurisy may proceed from a peritonitis and that the channel of infection is along the blood-vessels or lymphatics, and I see no reason why the pancreatic secretion should not be carried in a similar manner. The reddish areas of hæmorrhage which were noted in the fat of the mesentery, which were similar in size and form to the areas of fat necrosis, suggested that the factor causing the fat necrosis was carried in the blood-vessels.

In Case 2 the previous history of abdominal pain and indigestion and the acute onset with pain suggested perforating gastric ulcer as the most likely diagnosis to explain his symptoms and condition. The fulness in the upper part of the abdomen, the tenderness situated midway between the umbilicus and ensiform cartilage, and the curious area of dulness made me seriously consider the possibility of acute hæmorrhagic pancreatitis being the disease from which the patient was suffering. The previous history of jaundice and abdominal pain I did not consider to be against this view, as a few months before I had seen a case of acute hæmorrhagic pancreatitis giving a similar history (Case 1). At the necropsy on this case gall-stones were found and fully accounted for the previous attack of abdominal pain and jaundice.

The most striking point of interest about Case 2 and the one I wish to draw particular attention to was

[illegible], bile-stained, serous, sterile fluid [illegible]ty at the time of the operation. [illegible]nd many suggestions were made [illegible] fat necrosis was found and the pancreas did not appear to be enlarged, so that the diagnosis of acute hæmorrhagic pancreatitis was given up. It was suggested that possibly the bile-stained fluid might be accounted for by a perforating ulcer of the duodenum, but against this view was the absence of peritonitis, the clear character of the fluid, which proved also to be sterile, and the fact that the duodenum was carefully examined and found to be intact. The gall-bladder at the time of the operation was shown to be full of bile and intact, so that a perforation or rupture of this organ was excluded. The cystic duct was also normal but the bile ducts and the hepatic ducts could not be satisfactorily examined. We thought that possibly one of the ducts had ruptured and that the previous attack of pain and jaundice suggested a gall-stone as being the most probable cause of the trouble. At the necropsy a biliary calculus was found, but it was small and was not obstructing the flow of bile. The tissues in the neighbourhood of the bile-passages and pancreas had a swollen and sodden [illegible]

bile. I thought that the inflammatory and sodden condition of the tissues and ducts had allowed of an escape of bile into the peritoneal cavity by means of either the lymphatics
or blood-vessels, or [illegible]
and the urine both [illegible]
there was no gene[illegible]
point in favour of [illegible]
tity of bile-stained serous fluid was also found in the peri[illegible] the time of the operation, and at [illegible] in the neighbourhood of the bile [illegible] bile Another point of interest in Case 2 was the marked pigmentation of some of the cells and of the débris in the affected areas.

ON THE INFLUENCE OF FATIGUE ON THE MINUTE STRUCTURE OF THE KIDNEY AND LIVER:

PRELIMINARY ACCOUNT.

BY DR. GUIDO GUERRINI.

IN a fatigued organism there circulates, as is known, a very large quantity of particular substances which, when collected and spread through all the system, produce a certain condition the manifestations of which, perhaps, constitute in great part the symptomatology of fatigue. Now, given the presence in the circulation of such substances and given, on the other hand, the great ease with which the cells of the organ react in their minute structure to such conditions, it is not difficult to deduct that in fatigue also the organs will show some change in their cellules. It is just this hypothesis that I have sought to verify. The minute modifications of structure which I saw in the nerve-cells of the cerebral and cerebellar cortex have been already published, and the minute modifications of structure which I saw in the nerve cells of the spinal marrow will soon be published, but in the meantime in this preliminary note I give the results which I have already obtained as regards the kidney and liver—two organs which from the nature of their functions must certainly be affected by the presence in the circulation of the products of muscular exchange during fatigue. The technical part of the experiments was the same as that which I used for the study of the nervous system. I made
several dogs run wi[illegible]
by Grandis for the [illegible]
and temperature an[illegible]

[illegible]ve work. All the experiments [illegible]tain time (the same for all the animals) after the last meal. The results of my experiments are the following.

In the kidney.—The grosser modifications of structure are in the cells of the convoluted tubules and of the ascending part of the loop of Henle. The corpuscles of Malpighi and the collecting tubes are nearly always normal. In the affected cells the modifications of structure are, naturally, in relation with the degree of fatigue undergone by the animal. The more fatigued the dog was the more profoundly altered were the cells. In animals already much fatigued the following appearances may be observed. The protoplasma loses its usual aspect and becomes homogeneous and granular. It appears that the cellular body enlarges, sometimes little, sometimes so much that in a transverse section all the openings of the canals seem to be closed by the swollen cells. The edge between the cells becomes uncertain and sometimes disappears altogether. In animals still more fatigued the minute modifications of the cells of the convoluted tubules are, as I have said, much greater. It is seen, in fact, that the borders of the cells which surround the opening of the canals fray out and break and that the cellular protoplasm shows here and there rarefied points, vacuoles and cracks, and finally crumbles away into a fine detritus which collects in the opening of the tubules. In the midst of this detritus normal nuclei are sometimes found, sometimes lumps or granulous masses which stain like the nuclei. This degenerative process almost always attacks a certain number of cells, but sometimes it is seen only in a group of a few diseased cells which are in the midst of several normal ones.

In the liver.—The minute modifications of structure of the liver cells are much less than are those of the kidney cells, and they appear conspicuously only in the liver of those dogs in which the modifications of structure are the greatest They are as follows. From the beginning all the cellular protoplasm appears homogeneous, cloudy, and granular. The cellular body enlarges and the edge between the cells becomes uncertain and sometimes disappears altogether. Sometimes the little biliary canals are evidently compressed, whereupon the protoplasma of the liver cells appears rarefied, full of knots, spongy, and very dark from biliary pigment.

These are, in short, the results of my researches on the influence of fatigue on the minute structure of the kidney and liver. I will systematically continue the researches on the other organs.

A SERIES OF ELEVEN OPERATIONS FOR PERFORATED GASTRIC ULCER.

BY G. H. HUME, D.C.L. DURH., M.D., F.R.C.S. EDIN.,

(SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.)

THE 11 cases in the accompanying table have been operated upon during the past seven years and form a complete list of all the cases of acute perforation and gastric ulcer on which I have operated. The results agree in the main with the most recently published statistics and illustrate both the recent improvement in results and the dependence of this improvement on earlier opportunity of operating. A few remarks suggested by the cases may be arranged under the following heads.

Diagnosis.—In only one of the cases (Case 9) was there doubt when first seen as to the occurrence of perforation. The patient was seen in the night and had quite recovered from the collapse which marked the beginning of the illness. She was left till morning when the signs of commencing peritonitis were too evident to admit of further delay and she was operated on with good result. In another case (Case 3) there was doubt as to the origin of the general peritonitis which was fully developed. There was a history of a previous attack of peritonitis; the present illness was said to have begun with pain and tension in the right iliac region and it was uncertain which of the two—a perforated appendix or perforated gastric ulcer—was the source of infection. An exploration of the region of the appendix was first made with negative result; then the epigastric region was opened and the perforation was found. As a rule it is not difficult to make an early diagnosis. The past history of stomach trouble, TABLE OF 11 CASES OF PERFORATED GASTRIC ULCER OPERATED ON WITH SIX RECOVERIES.

No.	Sex and Age	Date of operation.	Interval between perforation and operation.	Situation of ulcer.	Treatment of peritoneal cavity.	Result.
1	F., 20	August 8th, 1893.	48 hours	Anterior wall near pylorus.	Flushed and drained.	Died.
2	F., 28	June 23rd, 1894.	Not stated in notes.	Not stated.	,, ,,	,,
3	F., 30	April 9th, 1896	48 hours	Anterior wall near cardia	,, ,,	,,

5	F., 16	Nov. 15th, 1896.	11½ ,,	Lesser curvature	,, ,,	Recovered.
6	F., 18	Dec. 1st, 1896.	43 ,,	Anterior wall.	,, ,,	Died.
7	F., 19	April 9th, 1898	6 ,,	,, ,,	,, ,,	Recovered
8	F., 18	August 19th, 1898	28 ,,	Greater curvature.	Wiped dry; no drainage.	,,
9	F., 26	April 12th, 1899	21 ,,	Pylorus	Sponged, no drainage.	,,
10	F., 18	Nov 5th, 1899	7½ ,,	Posterior wall, near lesser curve	,, ,,	,,
11	F., 27	March 19th, 1900	7 ,,	Anterior at cardiac end.	Flushed and drained.	,,

the sudden and severe pain with collapse, the epigastric tenderness and rigidity, with soon a slight rise of temperature, are indications enough to justify exploration. Vomiting occurred once or twice in all my cases and in at least one retching was continuous. When this occurs it is of evil import.

Interval since rupture.—In three cases the interval was from 43 to 48 hours and all these cases died. In another fatal case the interval between the occurrence of perforation and operation was the shortest in the list—namely, five and a quarter hours. In this case general peritonitis developed rapidly and was attended with great suffering. The course of this case I think is explained by the fact that shortly after the beginning of the attack a large dose of castor oil was administered. In the cases that recovered the interval ranged from six to 28 hours. In the instance in which 28 hours had elapsed the rupture had taken place when the stomach was empty, absolutely nothing by the mouth was allowed from the time of its occurrence, and at the operation there was so little extravasated fluid that only slight sponging was required.

Position and treatment of the ulcer.—In only one instance was the perforated ulcer found on the posterior wall of the stomach. It was found by turning up the stomach and tearing through the omentum. The treatment of the ulcer was the same in all cases. The edges were not excised but the opening was closed by a double set of Lembert stitches of catgut. A piece of omentum was laid over the site and fixed where this could be done.

Treatment of the peritoneal cavity.—The treatment of the peritoneal cavity has depended on the amount of extravasated stomach contents and general effusion. In Case 5, in which perforation had taken place soon after a meal and 11½ hours before operation, the abdomen was full of grumous fluid with particles of food, and the favourable result was thought to be due to the thoroughness with which the cavity was flushed out and drained. In three cases again the cavity was sponged dry where fluid existed and no flushing or drainage used. This is no doubt the preferable treatment and should be followed where there is only limited and local extravasation.

A CASE OF ANTHRAX.

By EDWARD ALBERT CLARKE, M.R.C.S. ENG., L.S.A.

THE following case which I have recently had under my care has a considerable resemblance to the one recorded by Mr. E. C. Bousfield in THE LANCET of Oct. 20th, p. 1133.

On July 14th, 1900, a man requested me to go to see his son who, he said, had scratched his forehead and got erysipelas in it. I went to see the case and found a lad, about 17 years old, who told me that on July 9th he had a pimple on his forehead which he had scratched. On July 12th it had become inflamed and swollen, but as he had no great pain he did not think it serious until the day of my visit, when the swelling had become so great that he could not see out of his left eye. On examining the left side of his head I found a black dry eschar, around which were an inflamed area and a circle of small vesicles. The skin on the left side of the head was swollen and œdematous and all along the border of the sterno-mastoid muscle the skin was raised, red, and swollen. Both upper and lower eyelids were swollen and were so œdematous that it was impossible for him to open the left eye. His temperature was 104° F., his pulse was in proportion, but he did not complain of any great bodily illness. At first sight I took the case to be one of erysipelas, but noticed the general good condition of the patient and the absence of pain, and whilst making up my mind I was struck by the appearance of the eschar and vesicles which seemed to resemble a plate or illustration that I had seen somewhere. The youth was a brush-maker and had been sorting hog bristles which had come from abroad. It then occurred to me that this was a case of malignant pustule and I determined that I would then and there without delay excise it. Having obtained the assistance of my friend Dr. R Bleasdale chloroform was administered and I made an elliptical incision round the eschar and vesicles about an inch and an half away from their outer border, cutting down deep to the bone and removing a portion of the muscle underneath, irrigating the wound all the time with a 5 per cent. solution of carbolic acid. The bleeding was very profuse as a number of small arteries were cut; this we allowed to go on unchecked until the whole piece, about two inches in its longest diameter and one and a half inches wide, was removed and then, by the aid of pressure forceps, strong carbolic acid, and hot water, it was got well under control. I then filled a hypodermic serum syringe with a 5 per cent. solution of carbolic acid and thrusting the needle beneath the edges of the wound for about one inch I injected the solution in eight or nine different places round the wound. A piece of lint soaked in the 5 per cent. carbolic acid solution was placed over the wound and an ice-bag was placed over all and instructions were left for the patient to have on the next day some strong beef-tea and a mixture containing five-grain doses of sulphate of quinine every three hours. On the following morning (July 15th) the temperature and the pulse-rate had fallen, and beyond the effects of the chloroform and severe shock the patient was doing very nicely; the swelling in the face and neck seemed to be slightly less. From this time to August 2nd I visited him daily, giving him plenty of nourishing food such as beef-tea, port wine, &c., and continuing the application of the 5 per cent. carbolic acid lotion and the ice-cap. He also had the quinine mixture, and during the whole of this time he improved daily. He then went to the seaside and eventually recovered perfectly.

I was unfortunately unable to have the portion of skin removed with the vesicles bacteriologically examined for anthrax bacilli. The interesting features of this case were: (1) that a case of anthrax has not been known in this neighbourhood before; (2) that the evidence distinctly pointed to the foreign bristles being the source of infection; and (3) that the prompt treatment by excision and thorough disinfection had been successful in a case which otherwise might have been fatal. Although there was no bacteriological examination I am convinced from the eschar and the vesicles, the œdematous swelling, and the slight pain in proportion to the local signs, that there was no doubt of the disease being anthrax.

Dukinfield.

AN INTERESTING CASE OF AMENORRHŒA.

By Wilfrid J. H. Hepworth, L S A.

I WAS consulted some months ago by a woman who was desirous of ascertaining whether she was pregnant or not. She was 23 years of age and had two children, the youngest being four months old. Her reason for thinking herself pregnant was that she had only infant was born, and that was On the other hand, she thought herself unlikely to be pregnant, for she had not experienced any of the sensations that she had noticed in her previous pregnancies, such as painful breasts, morning sickness, &c. Menstruation commenced at 12 years of age; there was then a period of six months' amenorrhœa and then regularity up to her marriage. Both labours were natural, but she did not nurse either child. She was preparing to pay a visit to the country when she consulted me and I advised her to come to see me again in six weeks' time (i e, when she returned home), as I could not find any physiological or pathological reason for the amenorrhœa According to promise she came to see me at the expiration of the six weeks, but it was to inform me that menstruation had returned two days after ain a month later. Three months ie to me with the same story of above She had been in London three months and had not once menstruated, though her periods had been regular whilst she was away. I recommended her to try another change of air. She did so and she was once more restored to regularity. She now leaves London for a couple of days each month when she at once becomes "unwell," though this is not the case if she remains in town. I have recommended her if possible to take up her abode in the district in which she resided previously to her marriage.

Old Basford, Nottingham.

SURGICAL EMPHYSEMA OF THE EYELIDS.

By Charles Leo Birmingham, M.D. R U.I.

ON Oct. 13th, 1900, a patient of mine, who was walking along a public road and carrying an open umbrella for protection from the rain had his umbrella suddenly blown against his face. One of the ends of a rib of the umbrella struck the right eye close to the caruncula lacrymalis. This caused a slight wound which did not bleed. There was no pain and my patient continued his walk. About three hours later he had returned to his dwelling and was sitting in an armchair removing his boots when he paused to blow his nose. Immediately his eye was closed with an inflated swelling of both the lids. I was summoned in great haste and arrived about 15 minutes after the onset of the swelling when I found that the enlargement of the lids was so great that not even the eyelashes could be seen. Gentle pressure on the lids gave rise to a "crackling" sensation. On hearing of the injury I at once diagnosed surgical emphysema of the eyelids. Without delay I began to apply gentle, slow, continuous pressure, using pads of lint soaked in boric acid solution beneath my finger ends. Within an hour I had the eyelids emptied of air. I left a pad of lint on the eye firmly fixed with a bandage Recovery was subsequently uninterrupted and the patient is now able to blow his nose again. There was slight epistaxis on the third day after the injury. My explanation of the occurrence of the emphysema is that the lacrymal apparatus was ruptured at the junction of the canaliculi and the sac None of the books on surgery which I have been able to consult records any case of injury such as I have described.

HOSPITAL PRACTICE,

BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb*, lib. iv. Prooemium.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.

A CASE OF SARCOMA OF THE SIXTH RIB IN THE REMOVAL OF WHICH THE PERICARDIAL AND LEFT PLEURAL CAVITIES WERE OPENED; RECOVERY.

(Under the care of Mr. C Whipple and Dr. H. W. Webber)

THE frequency of the occurrence of malignant disease of the rib is small, and especially rare is primary malignant disease in this situation It is generally necessary in attempts to remove the growth in such cases to open the adjacent pleura, or in exceptional cases the pericardium also may be involved in the course of the operation,[1] as in the case reported below.

A man, aged 46 years, a farm labourer, was admitted into the South Devon and East Cornwall Hospital on Sept 18th, 1900, for a tumour in the left side. The history given was that three months previously a small pimple formed over the position of the swelling; this broke and discharged matter owing (according to the patient) to the friction of his braces. A lump had appeared in the situation of the pimple which had gradually grown larger and caused him considerable pain. On admission he was seen to be a rather sparely-built man; he had formerly served in the army in India and while there had suffered from "fever and blood poisoning." Over the sixth rib, just external to the apex beat of the heart, was a tumour of the size and shape of a hen's egg with its long axis in the course of the rib; it was firm at the periphery, soft and semi fluctuating in the centre, firmly adherent to the rib, but not appreciably involving the skin. The skin over the tumour and for a little distance around it was marked with dilated veins.

On Sept 23rd, under chloroform, an incision five inches in length was made over the tumour in its long axis and the skin and subcutaneous fat were dissected off it. The rib was then cleared at points half an inch beyond the limits of the tumour and the bone with the tumour between these points was excised. In doing this the cavities of the left pleura and of the pericardium were freely opened, and the result was a hole some three inches by one inch, into which the apex of the heart bulged at each beat, and at the bottom of which the left lung collapsed (by the air admitted) could be seen lying. The screw-like mechanism of the heart in systolic contraction was well seen. The wound having been swabbed dry was closed by several interrupted fishing-gut sutures through the skin and the subcutaneous tissue. Dressings of sterilised gauze and wood-wool were applied. temperature had risen from °; he was unable to lie down n attack of bronchitis. The dressings required packing with wood wool, as much blood-stained serum had oozed through. On Sept 24th dyspnœa and orthopnœa were marked with frothy mucoid expectoration and inspiratory rhonchi The pulse was 100 per minute and the respirations were 32, the temperature having fallen to 99°. In the evening the temperature rose to 102 4° and the dressings, which were soaked with blood stained serum, were changed. On the 25th the morning temperature was 100 2° and the respirations were 36; dyspnœa and expectoration from bronchitis were rather troublesome. On the 26th the temperature in the morning was 99° and in the evening 99 6°; the respirations were 28 per minute. The dressings were changed again. On the 28th the evening temperature was 101°; the respirations were 28. On changing the dressings the edges of the wound were found to be somewhat red, so every other stitch was removed. A little slightly blood-tinged serum escaped with each forced expiration from between the stitches, evidently from the serous cavities. Hot boric fomentations were ordered every two hours to the wound. On the 29th the wound was cleaner and more healthy-looking, so dry dressings were re-applied. The morning temperature was 98° and the evening temperature was 99°; the respirations were 24 per minute. The bronchial attack was subsiding and the dyspnœa and expectoration were only slightly troublesome. From this date the patient gradually recovered and was discharged to the Pearn Convalescent Home on Oct. 15th. On discharge the wound was soundly healed, a somewhat depressed scar which bulged a little with each beat of the heart being present at the site of the operation. The venules round it were still dilated but to a much less extent than previously to the removal of the tumour.

---

[1] Quenu et Longuet: Les Tumeurs du Squelette Thoracique, Revue de Chirurgie, 1898, p. 365.

Remarks by Dr. WEBBER.—I am indebted to Mr. Whipple for kind permission to operate on the above case and to record the notes and I consider it worthy of record as in few cases has the pericardial cavity been freely opened in the manner above described. Dr. F. G. Bushnell prepared in our clinical laboratory microscopic sections of the growth which showed that it was a periosteal spindle-celled sarcoma with numerous hæmorrhages into its substance; its invasion of the costal cartilage was well shown at one part of the section.

PENRHYN HOSPITAL, BETHESDA.

A CASE IN WHICH A VARICOSE CONDITION OF THE INTERNAL SAPHENOUS VEIN WAS COMPLICATED BY IRRITATION OF THE INTERNAL SAPHENOUS NERVE; OPERATION AND CURE.

(Under the care of Dr. E. A. MILLS-ROBERTS.)

AT the present day the operation of excision of varicose veins is so very simple in performance and satisfactory in result that it is somewhat difficult to realise the hesitation with which surgeons formerly operated on veins and the fatal results which were only too often obtained. The mortality after excision is very small, probably less than 1 per cent., and the two most common causes are sepsis and embolism.

A man, aged 42 years, consulted Dr. Mills-Roberts in June, 1895, complaining of what he described as "severe pain" in the left leg. On examination he was found to be suffering from a varicose condition of the internal saphenous vein of the leg. The condition did not seem to be serious; the chief varices consisted of a considerable bunch in the region of the knee, there was an enlargement of the vein at the mid-calf, and there was a third enlargement contained in old cicatricial tissue about two inches above the internal malleolus. The painful area extended from about four inches above the internal condyle down the posterior and internal aspect of the leg to the ankle. There was a very distinct dark nodule in the cicatricial varix that, he complained, was acutely painful. The cicatrix was due to an injury received when he was 10 years old, the result of being kicked or trodden on by a horse, resulting in a necrosed condition of the lower third of the internal surface of the tibia. The necrosis and resulting ulcer took 12 months to heal and during this time "86 bits of bone were removed from it." He first noticed the varicosed condition of his leg when he was about 20 years old. The patient was employed as a slate quarryman and his wife kept a public-house where they resided. He confessed to free indulgence of stimulants but not to excess and he was never inebriated. He had a particularly healthy family history. The usual treatment of rest, bandage, and tonics was advised. Circumstances would not allow him to give up his employment. The treatment seemed to give him little or no relief, and he evidently thought not only that it was ineffective but that it rather aggravated the symptoms.

In the spring of 1899 the pain became so intolerable and severe that the patient was forced to give up his empl ment. While absolutely quiet he did not suffer muc comfort, but if he indulged in anything like activit who, h all the painful symptoms. In the aut erysipelas in again consulted Dr. Mills Roberts w about 17 years and found no evidence that the c pimple on his f

worse. It was unilateral, and from any evidence to trary the varicosity was confined to the length of extending from two inches above the ankle to the the region of the knee. The patient was urged to a radical operation and to have the varices remov seemed to be rather diffident about following this ad asked if there was any objection to his having advice. No objection was made. He in conseque sulted two Liverpool surgeons, who endorsed D Roberts's views, and returned seemingly satisfied and to undergo the operation. He was admitted to Hospital on May 4th, 1900, the operation being perf the 7th.

The patient having been anæsthetised an incisi five inches in length was made in a longitudinal and transverse direction, extending along the greatest of the bunch in the region of the knee, the mid-poi behind the inner tuberosity of the tibia. Aft trouble and very careful and prolonged dissection the saphenous nerve was found and was separated freel wards as far as the incision would allow, after whic gentle pulls were given. The vein was then tied at end of the incision and cut. The nerve in th time was kept out of harm's way by means of retractor. The dissection of the vein was continued four well-developed and enlarged branches being fo ning somewhat transversely towards the anterior m the leg. Five inches of the main trunk of the inner s vein were removed—that is, the length of the incis about an inch of each of the branches mentioned. was next directed to the mid-calf enlargement, means of an incision two and a half inches long, th of the vein was removed. The cicatricial varices *in statu quo*, Dr. Mills-Roberts, not feeling ju interfering with what had been a long-healing ulc incisions were drawn together with a few sutures dressed with carbolic oil and iodoform. The patien somewhat slow and uneventful recovery. His ten on the evening of the operation (May 7th) was 9 continued the same on the 8th, on the evening of had his bowels well moved. On the 9th the ten was normal and continued so. He was dismissed 16th perfectly convalescent and suffering no pa varicosity contained in the old cicatrix seemed to be and it was hoped that it would disappear. The no quite painless.

Remarks by Dr. MILLS ROBERTS.—1. What was pa interesting about the above case was the unusual se the pain which the patient suffered. I could only for it by the fact that his employment necessitated and often prolonged work in the kneeling positio times all day and often for four or five hours at a tin bunch at the knee must have pressed on the saphenous nerve, the pressure being considerably i during the time he was in the kneeling position. the ulcer he suffered from when a child the primary the varicose condition? 3. The blood lost during t tion was practically *nil*. 4. The delay in healing was due to the patient's "moderate alcoholic tendencies."

I saw the patient on July 24th. He was then q from pain and was perfectly able to resume his emp but on account of the liability of the recurrence of dition I have advised him to find some employm laborious. The varicosity in the cicatricial tissue appeared, there is no sign of the nodule, and absolutely no pain.

ROYAL UNITED HOSPITAL, BATH.—The s annual amateur performances in aid of the funds Royal United Hospital at Bath will be held at the Royal during the week commencing Dec. 10th. will be nine performances, and *Iolanthe* and *The S Scandal* are the pieces selected.

UNIVERSITY OF CAMBRIDGE.—Dr. G. E. H has been appointed an examiner in midwifery, C. T. R Wilson, F.R.S., an examiner in physics for egrees.—Professor Alexander MacAlister, M.D., as been elected President of the Cambridge Philo ociety.—The total of the donations paid, or prom University Benefaction Fund now exceeds £66, donations, a number are specially assigned ion of the new buildings for the medical school.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Laboratory Meeting.

A MEETING of this society was held at the laboratories of the Royal Colleges of Physicians of London and Surgeons of England on Nov. 6th, Mr. WATSON CHEYNE, the President, being in the chair.

Mr. WALTER EDMUNDS exhibited a dog which as the result of Total Extirpation of the Thyroid four days previously showed marked weakness and rigidity of the limbs with some tremor, and recession of the eyeballs.

Dr. W. D. HALLIBURTON and Dr. F. W. MOTT made a communication on the Chemistry of Nerve Degeneration, giving further results of their experiments in respect to the occurrence of choline in nerve degeneration and the chemical and physiological tests for that substance.

Dr. F. W. PAVY, Dr. R. L. SIAN, and Dr. T. G. BRODIE made a communication and demonstrated some experiments on Phloridzin Glycosuria.—Dr. PAVY remarked that when this substance was injected into the renal artery of a dog it produced the immediate appearance of a large quantity of sugar in the urine from the kidney on the same side and presently sugar appeared in the urine from the ureter on the other side. Whether taken into the stomach, or injected subcutaneously, or intravenously, phloridzin produced a very large quantity of sugar (amounting even to 10 per cent.) in the urine. The source of the sugar was an enigma. It might come from the general system or it might be produced by the action of the kidney on the blood. He referred to experiments in this subject by Zuntz.

Dr. A. E. RUSSELL and Dr. BRODIE exhibited some experiments upon the Cardiac Reflexes, showing that stimulation of the central end of the pulmonary branches of the vagus slowed the cardiac rate.

Dr. W. E. DIXON and Dr. BRODIE exhibited some experiments on Pulmonary Motor Mechanism, showing that pilocarpine produced muscular spasm of the bronchioles, and that ergot produced engorgement of the lung by constricting the peripheral arterioles.

GLASGOW SOUTHERN MEDICAL SOCIETY.

A Discussion on the Plague.—A Fresh Specimen of Hydatid Mole.

THE third meeting of the session of this society was held on Nov. 1st, Dr. WILLIAM WATSON, the President, being in the chair.

Dr. J. W. ALLAN introduced a discussion on the subject of the Plague and commented on the fact that the disease seemed to be dying out in Glasgow. Some people were inclined to say "supposed plague," a statement which in his opinion was foolish, for the advice of experts and bacteriological examination had proved the presence of the disease beyond doubt. So far Glasgow had been fortunate in the smallness of the number attacked and in the number of fatal cases. While, however, there remained even only a few cases in the city the position was still serious on account of the interference with commerce and shipping. Failure to detect and deal with the early mild cases might result in the development at a later stage of a more virulent form of the disease and also the conversion of the city into an endemic centre. According to Professor Simpson "two features are specially characteristic of plague, first, the slow, irregular, and gradual manner in which the disease acquires a hold over a locality into which it is imported and which may later become the scene of an epidemic; and secondly, the obscurity which often surrounds the earlier cases." From this statement it could be understood how important it was to deal quickly and thoroughly with early cases of the disease. Of the types of plague which he had seen at Belvidere Hospital the impression he formed as he saw them at the time was that they showed nothing characteristic until the local manifestation had been revealed. In one case the facies suggested to him typhus fever and in that of an old woman very ill had typhus fever. The lesson seemed clearly conveyed that bubonic plague might easily be missed unless it was expected. Dr. Allan then proceeded to describe briefly the various types of plague as enumerated by Professor Simpson and Mr. Cantlie of London—viz., (1) the larval, ambulant, or abortive type, or pestis minor; (2) the bubonic; (3) the pneumonic; (4) the intestinal; (5) the typhus; (6) the septic; (7) the nervous; and (8) the puerperal. In view of the different varieties of the disease of plague the diagnosis was no easy matter and the mild or larval type might readily be overlooked. Positive information, however, might be obtained by the aid of the microscope, and he would point out the value of "association" as a key in doubtful cases. What might be called the "house affection" or the "family connection affection"—the association by personal contact—was to be regarded as a valuable point in the diagnosis. Speaking of the variable nature of the malignancy of plague Dr. Allan gave some interesting information. Quoting from the "Memorandum on the Progress of Levantine Plague in 1878–79, including the re-appearance of the Disease in Europe," by Mr. N. Radcliffe, he showed how at first the disease at Vetlianka, on the Volga was of a mild glandular form, but that it was succeeded in time by a more virulent type, and finally ended in the pneumonic form in which the mortality was 100 per cent. This increased severity of the plague at Vetlianka was attributed to the approach of winter, which caused the inhabitants to pack themselves in their ill-ventilated stove-heated houses. With regard to the geographical distribution of the disease it had been known for years in India and China. Endemic in certain parts of these countries violent outbreaks spread from time to time. It was only too evident that the disease had now travelled beyond their boundaries probably by commercial relationships and had become pandemic. In conclusion, Dr. Allan remarked, seeing that plague could assume so many clinical aspects and that the possibilities of its re-introduction to Glasgow were neither few nor remote, it behoved the medical profession to keep on the alert for some time to come and to report promptly to Dr. A. K. Chalmers, the medical officer of health, all doubtful or suspicious cases. Let them not be lulled into a false security, for in that lay the greatest danger of all.—Dr. CHARLES E. ROBERTSON gave a short account of the illnesses of the patients Malloy who in hospital were recognised as the first cases of plague. After a consultation with Dr. Thomas Colvin, who had also visited the Malloy family, both concluded that they had an infectious disease to deal with and that the patients should be isolated in hospital. Accordingly the patients were then notified and removed as cases of doubtful enteric fever. Dr. Robertson further remarked that during his attendance on the family the cases presented features which, after excluding poisoning by irritant ingesta, suggested typhus fever to his mind.—Dr. THOMAS COLVIN remarked that as Glasgow had no special port sanitary medical officer to detect the introduction of infectious diseases from foreign ports the city's first line of defence was the general practitioner, to whom the present discussion was of the utmost importance. He thought that one practical outcome of the discussion would be a resolution to the effect that the sooner the corporation appointed a port sanitary medical officer the better for all concerned. In his opinion it was a great blessing for the community that so early in the outbreak of plague in the city they found no less than four cases of that disease in the same household. It was the association of the four cases that enabled him to say without any difficulty that whatever the exact nature of the disease was it must be infectious. A consideration of the same circumstance also must have helped to determine the provisional diagnosis of plague in Belvidere Hospital. Another important fact the plague brought out was how little was yet known of the exact nature of natural immunity from any of the infectious diseases. Charles Malloy was brought into the closest personal contact with his brother who died from the plague. He slept with him, ate and drank out of the same dishes, nursed him as best he could for the greater part of a week, and yet he did not take the disease. Mrs. M.—another case of Dr. Colvin's—was also brought into the closest contact with her daughter ill with the plague for 18 days and escaped the disease. On the principle of phagocytosis it might be said that they escaped because their leucocytes were able to digest the plague bacilli. But the question still remained, Why were their leucocytes able to do so, especially when it was known that both "contacts" were much run down for want of sleep and of proper food? Dr. Colvin then discussed at length the differential diagnosis of plague and enteric fever as seen in general practice, and in summing up said that in his opinion plague in the forms met with in Glasgow simulated many other diseases and the only valuable differential sign was the bubo. With regard to the bubo they had to exclude syphilis, gonorrhœa, and septic irritation. Finally, to complete the diagnosis the plague bacillus had to be found by bacteriological examination.—Dr. MATTHEW DUNNING gave an account of the cases of plague that he had observed in his practice during the epidemic.—Dr. A. K. CHALMERS in the course of his remarks gave an interesting history of the course of the plague in Glasgow. With regard to its similarity to typhus fever as regards the rash occasionally found, it was to be noted that the rash of plague resembled the late stage of the typhus rash and, moreover, was found earlier in the disease. While the plague as seen in Glasgow might reasonably be called a mild form of the disease it was yet true that the mortality was considerable, being no less than 47 per cent., and approaching the mortality of the epidemic in Cairo. In conclusion, Dr. Chalmers spoke at length as to the probable means of transmission of plague, the causes of its variable malignancy, and the value of serum injections.

Dr. JAMES WEIR showed a fresh specimen of Hydatid Mole which was examined with interest by the members.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 2nd, Dr. Gordon Black, the President, being in the chair.—Dr. L. A. Rowden read notes of a case of Descending Landry's Paralysis in a child. The child, a lad, aged 10 years, had whooping-cough in 1897 and cholera in 1898, but had since been in good health. On Sept. 14th, 1900, he slipped into a pit but seemed none the worse. On the 15th he appeared to have a stiff neck and on the 16th he did not seem very well and had a restless night. On the 17th there was paralysis of the muscles of the neck and of the deltoids with a temperature of 103° F. On the 18th there was complete paralysis of the neck, arms, forearms, &c., and intercostals, and later the muscles of the legs, face, and tongue became affected. The child died completely paralysed in all his muscles at 1 A.M. on the 19th from cardiac failure. The diagnosis was based on (1) progressive, symmetrical, motor paralysis; (2) no disturbance of sensation; (3) absence of rigidity, twitching, pain, or tremor; (4) mental functions unimpaired; and (5) no loss of control over the emunctories. There was no evidence of scarlet fever or diphtheria in the case, and the fall seemed to be a coincidence, as there was no injury to the spine.—Dr. Wardrop Griffith supported Dr. Rowden in his diagnosis of Landry's disease and referred to other instances where the paralysis was descending instead of ascending. He argued that the simple conception of a lesion, organic or nutritional, passing along the cord was often at variance with the march of the palsy, as in many of the ascending cases the arms were affected before the trunk. On the other hand, a purely peripheral affection of the nerves, though it accounted for most of the phenomena of the disease, and notably for that variability in the combination of motor and sensory symptoms which Landry himself had pointed out, did not account for all, and the association of right-sided facial palsy with paralysis of the external rectus of the same side, which was observed in one undoubted example, pointed to a lesion of the closely associated border of the seventh and sixth cranial nerves. He favoured the view, therefore, that Landry's disease was due to a toxic process, affecting various parts of the nervous system in different cases, and in some instances leading to demonstrable inflammatory lesions.—The President, Dr. A. G. Barrs, and Dr. J. Campbell also discussed the case.—Dr. Rowden, in reply, pointed out the similarity between Landry's paralysis and infantile paralysis and suggested that the former might also be caused by an acute anterior poliomyelitis but of a more regular and spreading character than in the latter.—Dr. E. F. Trevelyan read a paper on six, mostly severe, cases of Diphtheritic Paralysis, including remarks on albuminuria and ataxia in diphtheritic paralysis and on the prognosis and treatment of this affection.—Dr. A. G. Barrs spoke of the importance of complete rest in bed until the knee-jerk had returned in cases of diphtheritic palsy in which it was absent, for so long as the knee-jerk was absent the patient was the subject of diphtheritic palsy. He also referred to the importance of avoiding all restrictions in diet even in the acute stage of the disease beyond those imposed by the difficulty in swallowing and the loss of appetite inevitable to an acute infective state.—The President, Mr. J. W. Draper, Dr. A. Christy Wilson, Dr. S. Lodge, jun., Dr. H. J. Campbell, and Dr. J. E. Eddison also took part in the discussion.—Dr. Trevelyan, in reply, thought that the time of the re-appearance of the knee jerk was too variable and sometimes too delayed to be taken as a guide in the question of rest.—The following cases, pathological specimens, &c., were shown:—Dr. Gordon Sharp: Some New Drugs.—Mr. E. Ward: (1) A Mauser Bullet Wound of the Lumbar Region received at Willow Grange; immediate paraplegia; recovery after a long interval; and (2) a case of Gastro-jejunostomy, with illustration of a Method of Using Murphy's Button.—Dr. A. G. Barrs: (1) Gangrene of the Lung; (2) Retro-peritoneal Growth; and (3) Tuberculous Disease of the Suprarenal Capsules.—Mr. W. E. Bennett (Otley): A patient who 10 years ago was believed to be the subject of Intracranial Tumour.—Mr. B. G. A. Moynihan: (1) Four cases of Molluscum Fibrosum in the same family; (2) Tumour connected with the Vagus Nerve removed from one of the above patients; (3) a Skiagraph and Plaster Cast of a Sub-astragaloid Dislocation of the Foot; (4) a Skiagraph of a case of Club Hand; (5) a case of Hypertrophic Osteo-periostitis following Gonorrhœa; and (6) a large Fibro-cystic Tumour of the Uterus removed by Kelly's operation.—Dr. T. Wardrop Griffith: (1) Premature Closure of the Foramen Ovale; (2) Fragilitas Ossium; (3) Raynaud's Disease associated with Ichthyosis; and (4) Lupus almost completely cicatrised.—Mr. Lawford Knaggs: Intestinal Obstruction resulting from an operation for Radical Cure of Hernia and depending upon a congenital abnormality.—Mr. Mayo Robson: Chronic Osteitis and Abscess of the Femur.—Dr. Barrs and Mr. Lawford Knaggs: A case of Duodenal Stricture in a youth, aged 17 years; pyloroplasty.—Dr. J. B. Hellier: (1) Pregnant Uterus with Myoma removed by Abdominal Hysterectomy; and (2) Bilateral Ovarian Abscess removed by Abdominal Section.—Dr. E. F. Trevelyan: (1) A case of Juvenile Phthisis in a girl, aged 14 years, who had been under observation for some years; and (2) A case of Hemiplegia of slow onset in a syphilitic subject; improvement under anti-syphilitic treatment.—Mr. H. Secker Walker: A case of Rodent Ulcer of the Orbit treated by removal and skin-grafting.—Mr. C. J. Wright: Parts from a case of Ectopion Vesicæ with Absence of the Large Intestine; the child lived five days.

PLYMOUTH MEDICAL SOCIETY.—A clinical meeting of this society was held on Oct. 27th, Mr. G. Thom, the President, being in the chair.—Staff-Surgeon W. M. Craig, R.N., showed a young man who four months previously sustained a Fracture of the Lower End of the Humerus and subsequently exhibited signs of Divided Musculo-spiral Nerve. This nerve was exposed between the supinator longus and the brachialis anticus, the distal portion being involved in callus; after freshening the ends they were connected by means of two inches of each sciatic nerve of a freshly-killed rabbit, laid side by side and fixed with fine silk. Now, two months after operation, there was a decided increase both in movements of wrist and sensation.—Mr. W. L. Woollcombe showed: 1. A man, aged 35 years, on whom he had operated four months previously for Malignant Disease of the Transverse Colon with almost Complete Obstruction, removing eight inches of the transverse colon with omentum and four inches of jejunum which had become adherent to, and infiltrated by, the growth. The small bowel was united by means of a Murphy's button and the large by Mayo Robson's bone bobbin. Several infected glands lay in the meso-colon, one close back against the pancreas, and this necessitated removal of a large wedge of meso-colon. The operation was completed in less than two hours, and during it five pints of saline solution with one ounce of brandy and ten minims of liquor strychniæ were given intravenously. Between the fifth and seventh days a slight leakage occurred from the colon and a localised collection of pus formed which was evacuated. The button passed on the nineteenth day. Five weeks after operation the patient weighed 8 st. 13 lb. He now weighed 11 st. 8 lb., a gain of nearly 3 st. Motions were formed and of the size of a working-man's thumb. 2. A coal porter, aged 35 years, the subject of Double Popliteal Aneurysm, each with a false sac. Pain was first noticed two weeks before coming under observation, when his leg resembled a large, rapidly-growing sarcoma of the head of the tibia with glazed and discoloured skin over it. However, a few days produced such a change that leaking aneurysm was diagnosed. The sac was laid open and the vessel was secured on either side of the opening. Blood had burrowed all over the calf and produced much disorganisation of muscles. It was subsequently found that a portion of vein had been removed with the artery, being intimately adherent, and a few days later gangrene of the tips of the toes set in. Three weeks later, whilst still in bed, stiffness was complained of in the left calf and a similar condition was found to be starting there. Three days produced a great increase, so that the femoral artery was tied at the apex of Scarpa's triangle. Now, three months later, the result was excellent. Both knees were freely moveable, painless, and free from swelling or pulsation. The toes had not yet completely separated, but there was no spread of gangrene. The man was healthy, with no sign of syphilis or kidney mischief. —Mr. F. E. Row showed two patients on whom he had operated for Radical Cure of Hernia by clearing and removing the sac through a small incision, tying it as high as possible and allowing the stump to fly back. There were no sutures in the canal or ring. The first man was 55 years of age and had had the operation done on both sides three years ago. The second was a young man operated on three months ago.—Mr. C. H. Whiteford showed: 1. A Breast removed by Halstead's Method in which the operation was followed by sloughing of part of the axillary flap. It was suggested that this flap should be reflected at the end instead of early in the operation, and that the preliminary incision should not be carried into the fat. *The operation lasted four hours,* was well borne, and was followed by neither shock nor sickness. 2. A Modification of Paul's Tube for Drainage of Distended Intestine, having an opening on either side instead of only at the end, thus obviating blocking of the opening by the mesenteric border of gut pressing against it.—Mr. R. H. Lucy read notes of a case in which whilst delivering a kidney for incision the pedicle tore through and the kidney (a useful one) was thus lost. The pedicle fortunately remained in the grasp of the *left hand and was secured without much* difficulty.—Dr. F. G. Bushnell showed: (1) Slides illustrating Diseases of the Uterus; (2) films illustrating Leucocythæmia, Pernicious, and Chlorotic Anæmia; and (3) lantern-slides of micro-photographs of Diseases of the Breast.—Mr. G. Jackson, secretary of the Devon and Cornwall Branch of the Incorporated Practitioners Association, drew attention to an attempt on the part of the Commercial Travellers Benevolent Association to establish a medical club in connexion with the local branch of the association with remuneration for the medical officer at the rate of 1*d.* per week per member, and gave notice that at the next meeting of this society he would move a resolution condemning their action and calling upon practitioners in the district to refuse to accept the *post of medical officer.* There was a general feeling that the rate of remuneration was totally inadequate to the status of the proposed members of the association and that gentlemen occupying the position of commercial travellers were not the class of persons who should be attended on contract terms at all.

BRITISH ORTHOPÆDIC SOCIETY.—A meeting of this society was held at the Royal Orthopædic Hospital, *London, on Oct. 27th.*—Mr. H. A. Reeves showed the following cases: (1) Contraction of Toes following Cauterisation of a Nævus of the Dorsum of the Foot, accompanied by Exostosis of the Tibia; (2) Paralytic Genu Valgum with Lateral Curvature of the Spine; (3) Congenital Talipes Equino varus, for which he had *removed* the *upper articular* surface of the astragalus; and (4) two cases of Talipes Calcaneo-valgus, *in one* of which he had performed Arthrodesis. It was important in such cases to straighten the contracted sole before proceeding to rectify the position of the os calcis.—Mr. Reeves also showed photographs of a case of Charcot's Disease of the Ankle in a woman 52 years of age. She could not walk at all. He removed the loose and degenerated articular cartilages and the patient left the hospital able to walk well with instrumental support.—Mr. Reeves also showed the Bones of the Foot and Lower Half of the Leg from a case of Congenital Absence of the Tibula, &c.—Mr. D'Arcy Power, Mr. Chisholm Williams, and Mr. Muirhead Little discussed the cases.—Mr. Reeves also showed photographs of a case of Paralytic Deformity of the Elbow and Wrist due to Congenital Hemiplegia. He divided the biceps and straightened the elbow, but a sharp attack of arthritis followed. The patient's age was 28 years. He divided the palmaris longus and flexor carpi radialis with excellent results. He wished to point out that it was seldom necessary to divide the deeper tendons in such cases, even when of long standing.—Mr. Muirhead Little showed a child, two months old, suffering from Congenital Talipes Calcaneo valgus and having a tumour (so-called hæmatoma) of the Left Sterno-mastoid. Labour had been tedious and difficult, but the head had presented and forceps were not used. He hoped to be able to keep the case in view to see if wry-neck followed.—Mr. D'Arcy Power referred to his investigation of this subject. Out of 50 or 60 cases of tumour of the sterno-mastoid only three or four patients came up for tenotomy afterwards.—Mr. Muirhead Little showed an apparatus designed to strengthen any group of Muscles of *the Ankle and Foot by means of Voluntary Exercises.* The resistance to be overcome was furnished by means of weights attached to cords running over pulleys. He demonstrated its use on a child and pointed out that it was useful in all cases of talipes, when there was not too extensive paralysis, and also for flat feet. To encourage children to use it an electric bell was fitted, which was so arranged as to ring when the weight was lifted far enough.—Mr. A. H. Tubby read a paper on the Treatment of Deformities of the Hand and Fingers. As regards Dupuytren's contraction, he had found that open incision and dissection of the thickened fascia and its removal as far as possible gave good results in suitable cases, but the surgeon himself must see that aseptic conditions were attained or the result would be bad. *All bleeding must be quite stopped before the* wound was closed. Careful asepsis must be persevered with until every scab had disappeared. As regards club hand, he had not operated on such cases, preferring to treat them by splints. If any operation were needed he should prefer M'Curdy's. Mr. Tubby then discussed the functional prognosis of tendon suture in the hand, &c.—Mr. Noble Smith and Mr. Little spoke, and Mr. Tubby replied.

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY.—The first meeting of this society for the present session was held on Nov. 1st, the retiring President, Dr. H. Brunton Angus, being in the chair. The following officers were elected for the session:—President: Dr. Frank Hawthorn; vice-president: Dr. Ogden Watson Ogden; treasurer: Dr. W. E. Alderson; secretary: Mr. T. G. Ouston; committee: Dr. R. P. R. Lyle, Dr. T. Beattie, Mr. G. Foggin, and Dr. A. M. Martin.—Dr. Angus showed a man, 58 years old, with a large Pulsating Tumour on the Top of the Head. There was a history of severe blows on the skull eight years and one and three-quarter years before. At this latter period the growth was explored and removed by Mr. F. Page, who found it, after trephining the skull, to be outside of the dura mater. The growth was a pure angeioma but recurrence had gradually taken place. No primary cause, such as a thyroid tumour, could be found, but Dr. Angus considered the growth to be a secondary one.—Dr. R. A. Bolam, Dr. Beattie, and Mr. Ouston discussed the possible origin of the growth.—Mr. W. H. Vickery showed a child, *nine months old, from* whose thigh a Lipoma weighing 12½ ounces had been removed. The tumour (which was exhibited together with a photograph taken prior to operation) extended from the ischial tuberosity to the popliteal space. The only difficulties presented in removal were from its adherence to the great sciatic nerve and shock to the child.—Dr. Hawthorn, Dr. Angus, and Mr. Ouston commented upon the case.—Dr. Colles (for Dr. Coley) showed a boy suffering from symptoms resembling an advanced stage of Pseudo-Hypertrophic Paralysis. The feet were in a position of talipes equinus.—Dr. Beattie and Dr. Martin agreed in the above diagnosis as against anterior polio-myelitis.—Dr. Colles (for Dr. W. Beatley) showed a boy with Tumours in both Iliac Fossæ. *He also had enlarged lymphatic glands in the neck* which had suppurated previously and in one axilla. The tumours had remained of the same size for three months. There had been no rise of temperature for the same period and no alterations in the blood-cells or spleen could be made out.—Dr. Martin, Dr. Angus, and Mr. Ouston thought that the tumours were tuberculous glands, and Dr. Beattie, Dr. Bolam, and Dr. G. G. Turner favoured the view of lymphadenoma.—Mr. Foggin read a paper on Minor Eye Injuries and Antisepsis. Attention was drawn to the fact that no less than 12 varieties of bacteria had been isolated in the normal conjunctival sac, and to the many virulent organisms that caused inflammation with or without direct traumatism. The corneal epithelium should be treated as carefully as was the peritoneum. In treatment discs of atropine, cocaine, protargol, &c., were superior from an aseptic point of view to solutions kept ready made, whether used by surgeon or by patient, but gelatin discs were more liable to be septic than the compressed variety and were not so readily absorbed. Discs had the further advantage of exact dosage. Reference was made to fluorescine as a means of diagnosing actual corneal abrasions, also to the use and abuse of the eye-pad and bandage.

Sheffield Medico-Chirurgical Society.—A meeting of this society was held on Oct. 25th, Dr. Wearne Clarke, the President, being in the chair.—Dr. C. N. Gwynne showed a Large Growth, probably Papillomatous, removed from a Labium Minus.—Mr. R. Favell showed: (1) A specimen of Double Pyosalpinx; and (2) a Complete Cast of the Mucous Membrane of the Bladder passed per urethram six weeks after labour.—Mr. J. Menzies showed a large Branched Renal Calculus (oxalate of lime) removed together with the Kidney from a woman, aged 57 years. Special features of the case were the absence of hæmaturia and of characteristic attacks of pain during the six years which intervened between the onset of symptoms and the operation.—Mr. V. K. Blackburn showed the following specimens: (1) Duodenal Ulcer; (2) New Growth of Lung Perforating into a Pulmonary Vein; (3) Gastro-enterostomy for Dilatation of the Stomach; and (4) Primary New Growth of the Liver.—Dr. Sinclair White read a paper on the Operative Treatment of Pyloric Obstruction and illustrated it by exhibiting a series of patients on whom he had operated. Attention was called to the simple and safe way of demonstrating a dilated stomach by pumping air into it through a soft œsophageal tube. The differential diagnosis of the obstructing agency was often difficult or impossible until the abdomen had been opened, and even then certain cases of inflammatory thickening around the pylorus were liable to be taken for malignant disease. All patients showing definite symptoms of pyloric obstruction should submit to early operation if in a fit state to be operated upon. It had been conclusively shown that a large proportion of pyloric cancers remained for a considerable time strictly local growths capable of removal by pylorectomy at a risk to life which was not prohibitive having regard to the issues involved. In the treatment of non-malignant cases the surgeon had a variety of devices at his command, but the choice was gradually being narrowed to pyloroplasty and gastro-jejunostomy. While both operations gave excellent results pyloroplasty was theoretically the better of the two, but it was not sufficiently so to justify its adoption if it was less safe to life than gastro-jejunostomy. The ease, and to a large degree the success, with which pyloroplasty could be performed was influenced most of all by the mobility of the pylorus. If the pylorus could readily be withdrawn through the abdominal wound and isolated by gauze packing the operation was an ideal one and should be practised to the exclusion of all other methods; but if, owing to adhesions, the pylorus should be fixed at the back of the abdomen pyloroplasty became a tedious, difficult, and dangerous operation and should give place to gastro jejunostomy which could always be performed with the parts involved outside the abdominal wall.

Bristol Medico-Chirurgical Society.—The annual meeting of this society was held in the medical library of University College, Bristol, on Oct. 10th.—Dr. D. S. Davies gave the Presidential Address. After introductory remarks claiming the inter-relation of public health with medicine and surgery the address dwelt first on the problem of disease causation viewed from the several standpoints of the ancient and modern world—the ancient view, a superstitious dread of mysterious inexplicable disease; the modern view, a careful study of the life-history of causal parasitic organisms and of conditions causing or assisting their distribution—and epidemics as growth by geometrical increase along definite lines to be carefully traced back to initial cases, or, better still, to be checked first by making the conditions of life unfavourable to the parasitic habit, and secondly by dealing with individual first cases. The evolution of parasitic species was then discussed on the lines of Leuckart's and Payne's views, that these diseases originated from free living species, having adopted the parasitic habit under favourable environment and subject to the three parasitic laws of entrance, migration, and exit. Finally, the interacting causes, political, social, and medical, which were at work during the eighteenth century and led up to the modern conditions of life and labour, new social conditions under which the struggle with cholera had to be waged, unsuccessfully at first, but in time resulting—by continuance of the tendencies and altruistic endeavour of the previous century re-lighted by the pressing needs of the moment—in the beginnings of modern public health work, which meant far more than the mere care about communicable diseases, and had for its wider aims care of every class of the community, aims not yet fully realised but improving from day to day and full of promise for the future.—The honorary secretary (Mr. Paul Bush), the editorial secretary (Mr. James Taylor), and the honorary librarian (Mr. L. M. Griffiths) read their annual reports, the latter mentioning that there were at the present time nearly 20,000 volumes and 226 current periodicals in the Bristol Medical Library.—Dr. Barclay J. Baron was elected President-elect; Mr. Paul Bush was re-elected honorary secretary; Dr. J. Michell Clarke, Mr. J. Dacre, Dr. B. M. H. Rogers, Mr. G Munro Smith, Mr. James Taylor, and Dr. H. Waldo were elected to serve on the committee. Mr. Griffiths, Mr. Munro Smith, and Dr. Taylor were nominated to serve on the Library Committee.—Dr. Cyril H. Walker showed a patient with Sub-congenital Dislocation of the Lens, and Dr. A. Ogilvy made some remarks on this interesting case.

Rochdale and District Medical Society.—A meeting of this society was held on Nov. 1st. Dr. A. Wallace gave the presidential address on Medical Organisation and Reform. He pointed out how the medical student had impressed on him by his teachers the dignity and honour of his profession and how little he was told of the other side of the picture, quoting in illustration from a recent address by Sir Samuel Wilks to the students of Guy's Hospital. The consultant took little interest in the welfare of the general practitioner and knew little of the conditions under which general practice was carried on. Consequently, while the remedy for grievances lay in organisation, representatives chosen from the consulting class were likely to do little. Dr. Wallace thought that the number of organisations was overdone, and that the matter should be taken up by the British Medical Association, aided by small local societies. The dignity of the profession was all very well, but they could not live on dignity. With regard to the difficulties encountered in general practice there was, for example, the nurse with her thermometer and bag of dressings making irresponsible diagnoses and giving irresponsible advice. There was ambulance work helping to produce quack medical men. The unregistered man, said Dr. Wallace, had the best of it. Legislation, with few exceptions, was all in his favour. Coming to matters in which legislation was called for Dr. Wallace referred especially to death certification and the midwives question. These and other subjects could not be properly dealt with by the General Medical Council, itself composed of men who talked much of the dignity of the profession and little of its difficulties. More direct representation was wanted in the Council before it would recognise, for example, that the medical aid system, which might require a medical man to go three miles, pay a visit, and supply medicine for 3*d*., should be brought to an end. Credit was due to the Council for raising the standard of medical education, but it cared nothing for a man after he was qualified. The profession should organise, with small local societies as the units. Concluding, Dr. Wallace quoted from an eminent author: "Look not wistfully on the past, it cannot come back again. Wisely improve the present, it is thine. Go forth to meet the future without fear and with a manly heart."—Mr. J. Chadwick, Mr. R. B. Sellers, Mr. G. W. Malim, Mr. J. Rodley, and Dr. W. J. Kerr took part in the discussion which followed, and a cordial vote of thanks was then given to Dr. Wallace for his address.

Dermatological Society of Great Britain and Ireland.—A meeting of this society was held at 20, Hanover-square, on Oct. 24th, Dr A. J. Harrison, the President, being in the chair.—Mr. G. Pernet showed, for Dr. Radcliffe Crocker, a case of Acquired Syphilis in an infant, aged 15 months.—In the discussion which followed some difference of opinion was expressed as to whether this was really acquired or hereditary syphilis.—Dr. P. Abraham showed: (1) A case of Leprosy which had been previously brought before the society in which manifest improvement had followed treatment with chaulmoogra oil; (2) a case of Monilethrix, the hair of the scalp and eyebrows being affected; and (3) a case of Verruca of the Lips.—Dr. A. H. Stowers showed a case of Tertiary Syphilide of the Forehead and Face simulating Acne Rosacea.—Dr. A. Eddowes showed: (1) A case of Combined Psoriasis and Acquired Syphilis, eruptions characteristic of both diseases being present at the same time; and (2) a case of Acne Lupus.—Dr. Stowers deprecated the term "acne" being used to qualify this case which appeared to be lupus vulgaris with no relation to acne.—Mr. W. T. Freeman showed a case of Diabetic Eczema.—Mr. Pernet exhibited cultures and microscopical specimens illustrating (1) Ringworm, (2) Monilethrix Hairs, and (3) Sections of Skin from the case of Leprosy shown by Dr. Abraham in which the bacilli lepræ were numerous.

SOUTHPORT MEDICAL SOCIETY.—The annual meeting of this society was held on Oct. 10th.—The first annual report and balance-sheet were adopted, being considered highly satisfactory.—The following officers were elected:—President: Dr. Robert Harris. President-elect: Dr. Charles Pinkerton. Vice-President: Dr. G. C. Walker. Treasurer: Dr. F. J. Baildon. Honorary secretary: Mr. R. M. Little. Committee: Dr. Anderson, Dr. P. Ashworth, Mr. A. H. Baines, Dr. W. H. Barrett, Dr. Russel, and Mr. A. J. Popert.—The President then delivered an inaugural address entitled Some Observations on the History of the Profession in England during the Century. He described the gradual changes which had taken place in the position and status of the profession, the various enactments of Parliament, and the changes in the licensing bodies and their powers during this period.—The annual dinner was held at the Queen's Hotel on Oct. 31st, under the presidency of Dr. Harris. 40 gentlemen were present, including several distinguished guests from neighbouring towns, and the proceedings throughout were of a highly successful character.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—The inaugural meeting of this society was held at the General Dispensary on Oct. 10th; there was a large attendance of members and visitors, the President, Mr. G. B. Wray, being in the chair.—Dr. F. W. Mott, pathologist to the London County Asylums and physician to Charing Cross Hospital, gave an interesting address on the Selective Action of Poisons in Relation to Nervous Diseases, illustrating his lecture by means of limelight pictures and diagrams of neuropathic conditions.—At the conclusion of a pleasant evening a hearty vote of thanks, proposed by Dr. W. B. Ransom and seconded by Dr. C. H. Cattle, was accorded to Dr. Mott.

Reviews and Notices of Books.

Lectures on Medical Jurisprudence and Toxicology. By FREDERICK J. SMITH, M.A., M.D. Oxon., F.R.C.P. Lond., F.R.C.S. Eng., Physician to, and Lecturer on Forensic Medicine at, the London Hospital, Medical Referee to the Home Office. London: J. & A. Churchill. 1900. Pp. 396. Price 7*s.* 6*d.*

IN the preface the author explains that this book represents in detail, though not absolutely *verbatim*, the lectures which he has delivered at the London Hospital for some years. Dr. F. J. Smith writes the preface in an apologetic strain, but after a careful perusal of his work we can assure him that there was no need for him to adopt such a tone. The subject-matter is certainly condensed and we perfectly agree with him that "cram-books" are not to be encouraged, but in the book now before us the student will find all that he requires to know for the ordinary pass examinations. Not only so, but the busy practitioner will find it most useful for reference if he is suddenly called upon to give evidence before a coroner's or a magistrate's court in a difficult or obscure case. Should the case prove a serious or complex one experts will probably be requested to give to the counsel for the Crown the skilled help that is necessary.

Dr. Smith writes in plain and concise terms and there is no danger of misunderstanding his meaning. He introduces a new element into text-books of this nature and that is the frequent use of comparative tables or summaries. These are admirably put together and will enable the student to condense his knowledge in a satisfactory manner. A good example of such tables is found in one of the chapters on "Signs of Death." Difficulty not infrequently arises after death from violence in distinguishing between a bruise and a hypostasis; and, moreover, this point is frequently to be found in examination papers. By a careful study of the short explanatory notes given in the form of a table the student will easily be able to answer such questions, and in addition if he should require to make any practical use of such knowledge on a future occasion a glance at the table will at once recall the essential differences between the two conditions above alluded to.

In a similar manner are detailed the points to be noticed in making a post-mortem examination on a body found in the water and the principles which govern the management of "wounds" from a medico-legal standpoint. The portion of the book dealing with toxicology is also worthy of praise. This is always a subject of considerable difficulty to the student. The "method of occurrence," symptoms, fatal doses and post-mortem appearances are briefly (but at quite sufficient length) and succinctly recorded; Dr. Smith has wisely refrained from giving any but the most simple chemical tests. It is absurd for an ordinary medical practitioner to be expected to make a complete chemical examination in a case of suspected poisoning. Special aptitude and long years of experience are necessary before results can be obtained which would be of value in a court of law. This state of affairs is now generally recognised and expert chemists are delegated to make the required analyses.

We congratulate the author on the production of a useful text-book and can confidently recommend it to those for whom it is intended.

Practical Uranalysis and Urinary Diagnosis. By CHARLES W. PURDY, LL.D., M.D. Queen's University. Fifth revised and enlarged edition. Philadelphia, New York, and Chicago: The F. A. Davis Co. 1900. Pp. 392. Price $3.

THE fourth edition of this excellent manual was reviewed in these columns only about two years ago (Jan. 7th, 1899, p. 33), yet a demand for another issue has already arisen. This fact is the best evidence of its acceptation as a book of authority both on the clinical and practical sides of the subjects with which it deals. In the present edition some very important additions have been made. The work now contains an entirely new chapter on the microscope in its application to urinary analysis. In this we find careful details as to the management of the microscope and the preparation of the sediment for microscopical examination. Urinary casts are first described, epithelia and then the various forms of crystals met with in the urinary sediment, the study of the morphological features of pus and blood-cells in the urinary sediment being, of course, included. A short section upon bacterial examination concludes the chapter. Another feature of importance in the new edition is a description of the application of centrifugal analysis in urinary work. The author has devoted some years of labour to this interesting and rapid method of analysis and he regards centrifugal analysis as having now been elevated to the dignity of a scientific process which is justly entitled to rank amongst the so-called exact methods of analysis. New tables and improved methods have been introduced by means of which the determination of albumin, chlorine, phosphoric and sulphuric acids may be made "both relatively and absolutely with the degree of accuracy equal to that of any other method." In other respects the subject-matter of the which refer more particularly to the care of the insane" and is issued in a cheap and compact form. The key-note is struck in the first chapter: "the nurse for mental cases must clearly understand that the patients with whom she has to deal are suffering from bodily disease. ...... Mental derangement is as surely an indication of (brain) disease as are cough and expectoration in the case of lung affections." The post of nurse in charge of a mental case requires much tact and forbearance as well as nursing ability. Dr. Harding lays down the wise rule that for a private case of acute mania or restless melancholia with suicidal tendencies at least three nurses are required, though if the patient be very feeble two may be enough. Practical and judicious advice is given as regards the patient's rooms, clothing, and food, and with respect to feeding by the stomach tube. Symptoms of hernia, peritonitis, and distended bladder may be present without being as manifest as they would be in sane patients and should be regularly looked for. Unless compelled by necessity a nurse should never attempt to deal singly with an excited or violent lunatic but should always call for assistance. Instructions are given as to restraint, seclusion, the wet pack, the searching of suicidal patients at bedtime, and the bathing of patients. A short account of the forms of insanity brings to a conclusion a well-written, clear, and useful little work suitable for nurses and attendants.

JOURNALS.

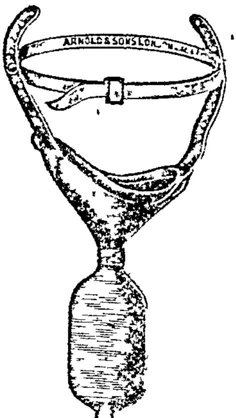
Edinburgh Review.—The October number contains a long article on "The Sick and Wounded in South Africa," based upon the debate which took place in the House of Commons on June 29th last on the management of hospitals in that country. The writer of the article concludes his critical and analytical history of the campaign in its medical aspects by claiming for his description that the truth, together with the lessons which it inculcates, has been set forth without fear or favour. He adds the expression of a hope that it may be for the last time that the officers of the Royal Army Medical Corps have to endure the most arduous labours and to battle with all the difficulties of an imperfect organisation. It is a thoughtful and well-balanced article, and if not altogether free from that "I told you so" spirit of wisdom which comes after events it is nevertheless written with an ability and a sense of responsibility which fully entitle it to serious and sympathetic consideration. And this is more especially the case because it does not deal with the subject in a merely destructive style of criticism, but in a constructive spirit also. It suggests for our imitation the system under which the Germans maintain the civil profession in touch with the army, and indicates some of the lines on which the Army Medical Service and the Royal Army Medical Corps might be remodelled with advantage. It would be impossible within any reasonable compass to take up all the points brought forward in the article in question. Nor is this necessary, for we make no doubt that those interested in the subject—and, considering its grave national importance and how it appeals to our common feeling of humanity, who is not?—will read it for themselves. Briefly summarised, the writer first takes up the question of unpreparedness. He refers to the evidence of the Director-General of Ordnance and others as to the total inadequacy of the medical reserve of stores and equipment in our possession immediately before the war to meet all the requirements of an army in the field; and mentions also the serious decline in popularity of the Army Medical Service. The service, he points out, is 60 below the figure which a late Director-General had already pronounced to be "perilously low" in numbers, while it has practically no reserve of medical officers for purposes of active service, so that the calling in of civil aid has been resorted to to an extent hitherto unparalleled. The writer next proceeds to give an outline of the situation in South Africa as far as it affected the hospital service. He refers to the eulogistic terms in which those who had been first of all sent out to the war had spoken and reported (and absolutely truthfully, we may parenthetically remark) of the hospital arrangements which they saw there. Then came the deplorable occurrences attributable to the epidemic outbreak of enteric fever, culminating in the appearance of Mr. Burdett-Coutts's letter in the *Times* of June 27th. The remainder of the article is taken up with the lessons inculcated by these occurrences and the remedial measures indicated. Here, while we agree with much of what is said, we consider the importance of the article detracted from because no stress is laid upon the fact that it was not until long after the campaign had begun that any correct notion had been formed on the part of the Government, the military authorities, or the nation itself, as to the probable nature, extent, and difficulty of the task that was being undertaken. It was consequently not upon one but upon all branches of the service that the results of our unpreparedness fell.

Bulletin of the Harvard Medical Alumni Association. Boston: Published by the Association. 1900. Pp. 67.—The objects of the Harvard Medical Alumni Association are "to advance the cause of medical education, to promote the interests and increase the usefulness of the Harvard Medical School, and to promote acquaintance and good fellowship among the members of the association." The tenth annual meeting was held in Boston at the Harvard Medical School on June 26th. The company at the annual dinner numbered 156. The president, Dr. David W. Cheever, in his address said that since the last meeting 119 new members had joined the society and that it now consisted of 1232 members. Dr. William T. Councilman delivered an address on the utility of laboratory work in the medical curriculum and on improved methods of teaching, especially of teaching pathology. Dr. James R. Chadwick gave a description and exhibited plans of the new building of the Boston Medical Library, now in process of construction, which is to be ready for occupancy on Dec. 1st next. The principal reading-room is 72 ft. long by 32 ft. wide; it is named Holmes Hall and contains a portrait and a bust of Dr. O. W. Holmes.

New Inventions.

AN INFANT'S REQUISITE.

The trouble and discomfort entailed on mother or nurse by the constant change of towelettes necessary for the proper care of an infant up to four months old can, I think, be avoided by the use of the appliance depicted in the accompanying illustration. Attached to a soft band round the waist and applied closely, so as to cover genitals and anus, the receptacle will contain both urine and fæces, and keep the infant from contact with either, no matter in what position the infant or appliance is placed. The contents cannot escape or flow upwards and there is no necessity to remove the child from the cot when the receptacle is full. The cap at the base can be unscrewed, which will allow the contents to escape. The appliance should be removed daily for cleansing, hot water with Condy's fluid being poured through. The saving of time and trouble and of the expense of the washing of dozens of diapers weekly should recommend the "Infant's Requisite." The makers are Messrs. Arnold and Sons, London.



Alexander Duke, F.R.C.P. Irel., &c.,
Cheltenham. Ex-Assistant Master, Rotunda Hospital, Dublin.

THE LANCET.

LONDON· SATURDAY, NOVEMBER 10, 1900

THE questions at issue between the medical staff of the National Hospital for the Paralysed and Epileptic and the board responsible for the management of the hospital are again before the public and must assuredly receive an early solution if irreparable damage is not to be done to the institution *And that this should occur would be a veritable* calamity, for the National Hospital for the Paralysed and Epileptic is known throughout the scientific world for its enlightened treatment of those whose afflictions it has been designed to meet If the work of this hospital be impaired the national prestige of this country in the world of medicine will suffer

Our readers may remember that the reply of the board of management to the circular letter issued by the medical staff to the general body of governors, wherein it was stated that the internal arrangements of the hospital were very unsatisfactory, was to call a general meeting of the governors of, and subscribers to, the hospital in the middle of the August holidays 16 persons attended this meeting, *and there is reason to suppose* that this small group was almost entirely composed of friends of the board of management, who received special invitations to attend The medical staff was not represented at the meeting, and the proceedings, which were reported *verbatim* in our columns, need no further comments from us than those which we have already made [1] No one who honestly desires to see harmony restored between the medical staff of the hospital and the board of management—a conjunction by which alone the effective working of the hospital will be secured—can fail to see that the meeting settled nothing The staff, when notice of the meeting was given, intimated the intention not to recognise the authority of a meeting so convened, and the board of management must since have found that the position then taken up by the staff meets with solid approval from all those best qualified to judge in the matter, But the board does not yet appear to understand the situation A letter addressed by Mr B BURFORD RAWLINGS, secretary director of the hospital, *to the editor* of the *Times* on Oct 18th states that the board now proposes that an inquiry into the management of the hospital by "an independent legal authority" should be undertaken at the earliest moment This is excellent well, as far as it goes, but such an inquiry does not in the least bit meet the case The charges made by the staff concerning the domestic condition of the hospital form only a part of the report which the staff has made to the governors, and the members of the staff have now intimated their intention not to consent to the investigation of one portion of the charges while the greater part are ignored *They refuse, and rightly,* to recognise that the decisions of the meeting of August 11th, *under which the inquiry by "an independent legal authority"* is to be made, have any weight with them, while the gist of their demands remains unnoticed The members of the medical staff demand representation upon the board of management, and if this representation is not conceded to them they will inevitably retire from their position as medical officers of the hospital, positions which they are proud to hold and which, we may add, they singularly adorn

That the determination of the members of the staff to be represented on the board of management of the hospital is not due to exaggeration of their own importance ought to be recognised by this time with the same clearness by the governors of the hospital and by the board of management as it is recognised by the medical world and all who are capable of forming a just opinion upon the situation A letter appeared in the *Times* of Nov 2nd, signed by the senior surgeons and senior physicians of all the hospitals in London having over 100 beds, by several past presidents of the Royal medical corporations by the medical men holding Court appointments, and by a few other leaders of medical thought, setting forth the opinion that the demand of the medical staff to be represented on the board of management of the hospital for which they give their scientific services is proper, and expressing a hope that the board and the governors will put an end to the controversy by granting the representation asked for The letter, which we reproduce this week in our columns, could have received the signature of every medical man of weight in the kingdom, but it was only desired that it should be signed by men able from their position to give their names as representatives of great public medical institutions or as occupants of some definite place in the public eye *We trust that those who* form the board of management will recognise the soundness of the advice that is offered them The time is come in the interests of the charity which they are presumed to administer for the public good when they should recognise the real state of affairs The contention is not about the cleanliness of a sheet on a certain bed or *the lunacy of a patient* on a certain date The effectiveness of a charitable institution of world wide renown and enormous public value is at stake The work of the National Hospital for the Paralysed and Epileptic can only be carried on properly if harmony is established between the medical staff and the board of management Such harmony will never exist until the board of management admits to its counsels representatives of the medical staff, so that the views of the lay and medical authorities can be properly exchanged without intermediary or risk of distortion upon any points whatsoever Never

* * *

WHEN students are attending a course of lectures on forensic medicine the lecturer attempts to impress upon them the importance of always making a complete post mortem examination in any case submitted to them by the coroner, all the cavities of the body should be opened even though sufficient cause for death is found in the cavity just opened Too often, however, this advice is forgotten , certain parts of the body are not examined, and when the medical witness submits himself to the questioning of the coroner or of counsel opportunities for advancing knowledge offered by the hospitals, while they were misunderstood by the public, were not adequately laid hold of by the students. A section of the public said that hospitals ought not in any way to serve as theatres of investigation. There had been much misdirected talk about hospitals being used for the purposes of experiment, but every touch of the surgeon, every counsel of the physician was an experiment, because it was not possible to be absolutely sure of the result, though the surgeon and physician were prepared to profit to the utmost by the teachings of that result. The factor of uncertainty might in certain cases be insignificant, but it could never be wholly absent, and it therefore might be said that there were performed day after day, in every hospital, a multitude of scientific experiments. Every such experiment was directed to the welfare of the patients and the teaching derived therefrom tended to diminish that great factor of uncertainty and to make the science of medicine less and less experimental and more and more efficacious. Sir Michael Foster regretted that the analysis of the phenomena of disease at the bedside, no less than in the post-mortem room, was apt not to be carried out in hospitals as completely as it should be. Such analyses could, he pointed out, only be carried on by means of thoroughly equipped laboratories in connexion with the hospitals, and the cost of these was as proper a charge on the funds of a hospital as the bill for drugs or surgical appliances. Much was heard nowadays about post-graduate study, and he suggested that it would most properly take the form of training men in the true methods of research so as to satisfy not only the demands of any examination but the demands of nature itself. The American graduates complained that they received very little post-graduate aid at the London hospitals and that the special institutions failed to supply them with what they wanted. They had, in fact, to go away from London, often against their wish, because it was impossible to secure in the metropolis what they could get elsewhere. If post-graduate study was so organised that the men were properly trained in investigations and inquiries, that would meet the wants of all and the graduates from the other side of the water would not fail to find in London what was required. These graduates could be directed and trained in a number of important problems and thus be educated in the right way of looking at medical truths and the final result would be an immense addition to our medical knowledge.

---

[1] THE LANCET, August 18th (p 492 and p. 551 et seq) and 25th, 1900 (p 590)

MASTERS, SERVANTS, AND MEDICAL MEN.

A NEWSPAPER report, erroneously as far as we know, has recently assigned to Mr. Fordham, one of the Metropolitan police magistrates, a dictum to the effect that employers are responsible for medical attendance upon their domestic servants. This, of course, is not the case, the employer only being liable who has called in the medical man or otherwise directly or indirectly undertaken to remunerate him. In 1795, it is true, Lord Kenyon was of another opinion, and held that a master was obliged to provide for his servant in sickness and in health and that he was therefore liable for medicines furnished to his servant while in his service. Eleven years before, however, Lord Mansfield had said in a case of this kind: "I don't applaud the humanity of the master. ...... I think, in general, a master ought to maintain his servants and take care of them in sickness, but the question now is, What is the law?" and the rest of the court had agreed with the Chief Justice in holding the master not to be liable. In 1802 one of the judges, hearing an appeal in which the above-mentioned judgment of Lord Kenyon was cited but not followed, expressed his belief that the humanity of his lordship had misled him, and that it must have occurred to him that if the master was not bound to provide medical assistance for his servant the latter would be left wholly destitute, while another judge who was a member of the same tribunal summed up the situation by saying, "It must be left to the humanity of every master to decide whether he will assist his servant according to his capacity or not." The view of the law laid down in this case[1] has, we believe, not been disputed, and we must accept it, qualified as it is by the opinions expressed as to the moral obligation upon the employer to see that proper medical aid is afforded to the servant, even if his doing so involves a demand upon his own pocket. We are aware that a servant earns higher wages nowadays and is upon a different footing with regard to his employer than when, as we find from the report of the case above mentioned as decided by Lord Kenyon, he was "part of his family," but the servant of either sex is not always even now able to defray the cost of proper treatment in illness, and is often unwilling to procure the best, or indeed any, medical advice, in cases where medical advice is a necessity and the intrusion of the quack or unqualified adviser may be fraught with serious consequences. Medical men, however, must not treat the domestic or other servant under any mistaken impression that the employer, as such, is legally bound to pay for the medical attendance or the medicine.

MEAT INSPECTION AND THE USE OF STERILISED MILK.

MUCH interesting information on the subject of meat inspection as conducted in four great centres of population will be found in a report recently presented by Dr. Henry O'Neill to the Markets Committee of the county borough of Belfast. This gentleman was appointed by the corporation of Belfast as a delegate to represent them at the Congress of Hygiene and Demography held in Paris last August, and he therefore devotes several pages to meat inspection as carried out in Paris, where there are no private slaughter-houses and where all animals intended for food must be slaughtered at the public abattoirs at La Villette, Grenelle, Vaugirard, or Villejuif. The abattoir at La Villette covers 67 acres, and in it 3000 oxen and cows, 1000 calves, and 10,000 sheep are slaughtered weekly, employment being thereby provided for about 1000 persons. The meat is examined by qualified inspectors under the superintendence of a veterinary surgeon, and if found to be healthy and good it is stamped with the letters "P.P.," meaning Prefecture of Police. Meat obtained from animals killed outside Paris, no matter how near the city, can only be brought into Paris through the appointed city toll gates and must be taken for inspection to the public slaughter-houses or to certain specified markets, where it is stamped if found satisfactory. Meat improperly admitted for human consumption is seized and either destroyed at the owners' expense, or if claimed for use in manufacturing processes it is subjected to appropriate treatment before being returned to them. In Berlin the method is somewhat the same. All cattle to be offered for sale in the city must be brought to the public abattoir, and the slaughtering of cattle anywhere else within the municipal boundary is absolutely forbidden. All dead meat slaughtered in the country or abroad and intended for human food in the city must be brought to the public abattoir and meat market for inspection. No butcher in Berlin may offer meat for human food which does not bear the official stamp. In London, on the other hand, there is no regular inspection of meat except in the market at Smithfield and all meat is held to be fit for food unless it has been condemned by the officers of the sanitary authorities. There is, in fact, no doubt that London receives diseased meat sent up from all parts of the country. In Manchester meat inspection in the abattoir and meat-market is conducted much in the same manner as in the City of London: there is no complete inspection of all meat and the meat which is inspected is not stamped. Dr O'Neill embodies in his report a number of useful suggestions for an improved method of inspection. In a separate report presented to the Public Health Committee of the county borough of Belfast he mentions the method of milk-inspection followed in Manchester and discusses the question of the municipal supply of sterilised milk as practised at St. Helens in Lancashire for rather more than a year past. These reports will be found useful by anyone in search of information on the subjects of which they treat.

THE LATE PRINCE CHRISTIAN VICTOR.

THE death of Prince Christian Victor from that most insidious of diseases, enteric fever, at the age of 33 years, was announced in a telegram from Lord Roberts at a time when London was rejoicing at the return of the City Imperial Volunteers, but, in accordance with the wish of the Queen and of other members of the Royal family, the public announcement of the sad fact was delayed in order that a gloom might not be cast over these rejoicings. Although the Prince was known to be seriously ill the announcement of his decease came as a shock to the country, and his death is sincerely mourned not only by the army but by every subject of our beloved sovereign whose grandson he was By strict attention to duty he earned the praise of all who came in contact with him, and during the operations in Natal under General Hildyard he was twice mentioned in despatches. In accordance with his wishes the deceased Prince has been laid to rest among his comrades at Pretoria.

TREATMENT OF SUPPURATIVE PERICARDITIS: "IDEAL PERICARDOTOMY."

THE *Boston Medical and Surgical Journal* of Oct. 18th contains an important paper on this subject by Dr. C. B. Porter. The line of reflexion of the pleura and pericardium is very variable. Even at the level of the fifth space the pleura will often be found behind the sternal border. Hence some of the methods which have been used for opening the pericardium—trephining the sternum approach through an intercostal space and epigastric incision—should be discarded as there is danger of wounding the pleura or diaphragm. After experiments on the cadaver Dr. Porter devised the following "ideal operation" to meet the following indications: (1) to avoid opening the pleural cavity; (2) to open the pericardium opposite the point where drainage will remain good after the sac has contracted; and (3) to secure free permanent drainage. An incision is made from the middle of the sternum outwards over the fifth costal cartilage to its junction with the rib. The soft parts are reflected from the cartilage with a periosteal elevator, care being taken not to wound the pleura on the under surface. The cartilage is divided with a bone forceps near the rib and sternum The internal mammary vessels thus exposed are ligatured in two places and divided. The triangularis sterni is separated from the sternum and pushed to the left. If fat is encountered a little careful dissection with a director exposes the pericardium, which is much thicker than the pleura An aspirating needle is introduced (if this has not previously been done) to corroborate the diagnosis. If this is confirmed the knife should follow the needle. The pericardial incision is best made downward and outward, beginning close to the sternum. An operation essentially identical with this has been performed in five cases by Brentano.[1] The edges of the incision should be stitched to the soft parts. The writer recommends that irrigation should be used in all cases to remove masses of fibrin which may lie at the bottom of the cavity. The fluid must be warm and have a free exit, under which conditions no harm has been done in the reported cases—half of the total cases The wound should be irrigated daily, and if the patient's strength permits it he should be turned on to his abdomen to facilitate drainage. 51 cases of incision of the pericardium have been reported. The pericarditis was purulent in 46 cases, rheumatic sero-fibrinous in two, hæmorrhagic from trauma in one case, and serous in two cases. The etiology was as follows: pneumonia with and without empyema (14 cases), broncho-pneumonia—in a child—(one case), osteomyelitis (five cases), wounds (four), blow on the chest (one), periostitis (one), necrosis of nasal bones (one), septic arthritis of knee (one), septic throat (one), abscess of buttock (one), empyema without pneumonia (five), pleurisy of doubtful origin (two), typhoid pleurisy (one), influenza (one), tuberculosis (two), rheumatic fever and endocarditis (three). In the 51 cases there were 31 deaths—a mortality of 60 per cent. Recovery took place in the two cases of serous pericarditis. In the 14 cases of pneumonia there were four recoveries. Dr. Porter's conclusions are as follows: 1. Pericardotomy is indicated in all cases of suppurative pericarditis. 2. Because of the varying relations of the pleura and the anterior position of the heart when the pericardium is distended aspiration is a more dangerous operation than open incision. 3 Pericardotomy can be done quickly and safely by resection of the fifth cartilage, in many cases under local anæsthesia. 4. In many cases of serous effusion open incision offers less risk and a speedier cure than aspiration.

THE REGISTRATION OF NURSE-CHILDREN.

THERE is a defect in the statute-book to which we, and not we alone, have repeatedly directed attention. It is the absence of any provision for regulating the boarding-out of single nurse-children. For some reason, probably more imaginary than real, it has been assumed that the interference of law is required only where two or more children are concerned. The case is one in which logic has been too little regarded. For the interest of one child is in no wise different from that of several, and though it may appear at first sight that the danger of neglect or other form of malpraxis is less in the former than the latter case experience has often shown, and still continues to show, that it may be equally great in both. Infant children are not very often sent out to board in this country. When it happens that they are so boarded the motive is to be found only too commonly in the apathy or the ill-will of parents to whom their mere existence is a disgrace. It is now generally recognised that, as a rule, the child is illegitimate which becomes the prey of the baby-farmer. If these two be brought together no second infant is needed to insure the inevitable result. In a case recently unearthed by the National Society for the Prevention of Cruelty to Children a child, aged six months, was found in the possession of a drunken "nurse" the mother of three children, all of whom, as well as the nurse child, were shamefully neglected. The woman was very properly condemned to six months' hard labour, but it is noteworthy that her conviction was only indirectly due to her farming the nearly starved infant. This most important part of the delinquency would probably never have been known but for the inquiries of a School Board officer after her own children. Such a fact—and it is by no means an isolated example of its kind—should go far to convince any doubter that the registration of single nurse-children is both necessary and just. What objection can be brought against this needful provision it is difficult to see. We feel certain that if enacted it would meet with approval in all classes of the community, and we trust that it will not be forgotten among the earlier domestic measures of the new Parliament.

COMPLIMENTARY DINNER TO SIR GEORGE HARE PHILIPSON.

AT a meeting of the Southern Council of the Durham University Medical Graduates' Association held at the rooms of the Medical Society on Nov. 1st it was unanimously resolved to invite Sir George Hare Philipson to a complimentary dinner at the Café Royal, Regent-street, on Thursday, Nov. 29th. All graduates of the University who are members of the association in the south are invited to join in honouring the guest of the evening, who is one of the founders of the association and one of its strongest supporters. Full particulars may be obtained from the honorary secretary for the south, Dr. T. Outterson Wood, 40, Margaret-street, Cavendish-square, W.

DOWLING *v.* DODS.

TOWARDS the end of last June an action was brought by Miss Agnes Dowling, a nurse, against Mr. Louis Ferdinand Dods, a medical man, for libel. The circumstances were reported in THE LANCET and may be remembered by our readers. The alleged libel was contained in a document purporting to be a certificate of lunacy and addressed to the local relieving officer. The defendant pleaded justification and privilege. The learned judge before whom the case was tried, Mr. Justice Darling, held that the occasion was privileged, but the jury found for the plaintiff, awarding her damages to the amount of £100. The plaintiff in her evidence showed herself to be the victim of dangerous hallucinations, so that the result of the trial surprised the medical profession and the public considerably, and a different issue upon appeal was anticipated. This week, before the Master of the Rolls, Lord Justice Collins, and Lord Justice Stirling, an application was made by Mr. Dods for judgment or a new trial. An attempt was made on Miss Dowling's part to show that Mr. Dods had been actuated by malice, but the judges held that there was no evidence of malice and judgment was entered for the defendant with costs. We congratulate Mr. Dods upon this result. We are satisfied that his conduct in the matter had its origin in a well-founded belief that Miss Dowling was of unsound mind and a source of danger to the community.

GENERAL PARALYSIS IN THE NAVY.

IN the November number of the *Edinburgh Medical Journal* Surgeon F. H. A. Clayton, R.N., assistant medical officer at the Royal Naval Hospital, Yarmouth, publishes an analysis of the statistics of general paralysis as observed in the Royal Naval Asylum for a series of years, and discusses the question of its etiology, with especial reference to sexual excess, syphilis, and alcoholism. An investigation of this disease as it occurs in the navy possesses the advantage that the inquiry is limited to a distinct class of men who are particularly subject to it, whose medical history since entry has been recorded, and whose physical condition, environment, and even mental characteristics are much alike. That seamen are more liable than officers to this disease appears from the fact that of 274 officers admitted in the last 25 years only 48 were paralytic cases, 12 of whom were warrant officers coming originally from the seamen class, whereas of 839 men 188 were paralytic cases. At present among 27 commissioned officers in the asylum there is no case, but, on the other hand, four out of six warrant officers and 18 out of 97 men come under that head. With respect to etiology Surgeon Clayton summarises his conclusions as follows: "Altogether, one inclines to accept the view that although syphilis or its toxins in many cases, by interference with nutrition, render liable to general paralysis many persons otherwise free, there is no evidence of direct connexion. The influences which act remotely are usually conditions tending to interference with nutrition and to promoting the growth of less highly organised tissues while the proximate influences probably act by lowering vitality. A 'specific' cause, as yet unknown, capable of developing the disease *per se*, though often aided by various factors, and which usually selects those apparently most healthy and vigorous both in mind and body, seems to be indicated by all the evidence." As is well known, general paralytics always become bed-ridden and in the concluding paragraphs of his article Surgeon Clayton gives some useful hints for the prevention of bed-sores.

HUXLEY MEMORIAL LECTURE.

To commemorate the anthropological work of the late Professor Huxley the council of the Anthropological Institute of Great Britain and Ireland has decided to found a public lecture, which will be called the "Huxley Memorial Lecture," and will be given annually at the opening of the winter session of the institute. The first Huxley Lecture will be delivered by the Right Hon. Lord Avebury, D.C.L., LL.D., F.R.S., and is announced to take place on Tuesday, Nov. 13th, at 8.30 P.M., in the Lecture Theatre of the Museum of Practical Geology in Jermyn-street, S.W., which as the scene of so much of Huxley's most impressive teaching, was felt to be the most appropriate place for such a ceremony, and has been placed for the occasion at the disposal of the Anthropological Institute. It is understood that Lord Avebury will take as the subject of his discourse Huxley's own contributions to anthropological science: a theme on which as a friend and colleague of Huxley, as himself a distinguished anthropologist, and as the first President of the Anthropological Institute he has peculiar authority to speak. Applications for tickets of admission should be addressed to the secretary, the Anthropological Institute, 3, Hanover-square, W., as early as possible.

DEATH UNDER NITROUS OXIDE.

A RECENT inquest held by Dr. Danford Thomas, the coroner for the county of London and Central Middlesex, upon a patient lately in the Great Northern Hospital, illustrates one of the few dangers which are incidental to the use of nitrous oxide. The patient, a man, aged 36 years, was admitted as an out-patient, declining to be taken as an in-patient, at the Great Northern Hospital. He was then suffering from suppuration in the structures of the neck. The swelling extended from the left ear round the jaw and well beyond the middle line. The left tonsil and structures between it and the outside were swollen and inflamed. As incisions were urgently called for the man was made to inhale nitrous oxide. This was given by one of the officers of the hospital who gave the gas diluted with air at first, but subsequently he employed pure nitrous oxide. An extremely small quantity of gas—a bag and a quarter—is said to have been inhaled and it is expressly stated that no re-breathing from the bag took place. When the ocular reflex was still present the incision was made and respiration ceased. It is said to have disappeared after the "excited stage." Possibly the man was never fully under the gas and the cessation of respiration was due to syncope from fear in the semi conscious condition. However, the house surgeon stated at the inquest that the death was due to asphyxia. At the necropsy œdema of the larynx was found to exist and the lungs were congested. Tracheotomy, which was performed as soon as the breathing failed, was unsuccessful and respiration never returned. These facts certainly point to heart failure as an element in the case. In all conditions in which the upper air passages are swollen and œdematous and respiration is hampered nitrous oxide is contra-indicated as it is liable to intensify the obstruction by promoting venous engorgement. That nitrous oxide is the safest of all known anæsthetics is now accepted on all hands, but as it is commonly given with little or no air there is a tendency to asphyxial complications, themselves not a necessary part of nitrous oxide anæsthesia. If there is a pathological state present in the patient these complications may become dangerous. Again, incomplete anæsthesia under nitrous oxide is a source of peril. In it heart failure not infrequently occurs and has on several occasions proved fatal. The death was no doubt asphyxial in so far as the œdema of the glottis probably under the gas closed the air passages completely; but whether death would have occurred if the nitrous oxide factor could have been eliminated is, we think, a question open to argument. As we read the report it appears that either too much or too little of the anæsthetic was given. We are certainly imputing no blame, for such cases are extremely difficult to deal with and the judgment of even the most expert anæsthetist might lead him astray in his endeavour to do his best for his patient.

MARGARINE, WINE, AND TOMATOES.

MODERN adulteration is a fine art and there is little doubt that fraudulent practices often escape detection. Any proposal, therefore, to make detection more certain must be very carefully considered. Some time ago it was suggested that margarine should be compulsorily coloured in order that it may be distinguished from the yellow colouring of butter. Of course, if margarine manufacturers were compelled to make their margarine blue or pink there could be no possibility of mistaking this substitute for butter. A better proposal, however, would appear to be that of adding an infinitesimal proportion of phenol phthalein to margarine, which would give the margarine no colour at all until it were made alkaline by adding soda to it, when it would turn a brilliant carmine The question remained to be answered, however, as to whether the presence of such a minute amount of coal-tar derivative would be injurious. It has recently been ascertained that even large quantities of phenol phthalein are quite harmless and produce no unpleasant symptoms whatever. This device could be applied to a number of food substitutes, the recognition of which as such would thereby be much facilitated It is well known that low-class wines are frequently worked up from the residue of crushed grapes after the bulk of the juice has been expressed. Such wine, which is known as marc wine, may or may not be wholesome. It is certain to be of feeble quality. At any rate, it is desirable that the detection of such wine should be easy. Phenol phthalein added in the proportion of 1 part to 100,000 of wine would not make the wine a bit more unwholesome, whilst the addition of alkali to the wine would result in a brilliant red colour which would brand at once its origin. Injury to health may obviously arise by the consumption of unsound or unripe articles of food, and the worst form of fraud is that in which a colouring or preservative agent is used to conceal bad characteristics It would appear, for example, that tomatoes are cunningly coloured in order to make them look attractive and ripe The danger of consuming these articles is great, for it is well known that unripe and unsound food is constantly a source of diarrhœa and other serious disturbances. This proceeding is not justified by the fact of the colouring matters being possibly innocuous. Amongst the colours so employed are the coal-tar colours and cochineal, both of which may be detected by certain chemical tests. The tomatoes generally coloured are those which are preserved. It is well that the whole subject of the artificial colouring and preservation of food is receiving the attention of a Departmental Committee, whose labours we hope will shortly be finished, and whose pronouncement, we trust, will give power to exercise a greater control over this form of tampering with food.

A PARISH MEDICAL OFFICER FOR SOUTH UIST.

IN our issue of Oct. 20th there appeared an advertisement for a medical officer for the parish of South Uist (Northern Division). We do not desire to put obstacles in the way of South Uist obtaining a competent medical officer; it is an isolated parish and its medical officer will have great responsibilities; but though we have inserted the advertisement we think it our duty to remind all candidates that the Parish Council of South Uist was responsible for the scandalous treatment of Mr. J. Lamont to which we have made frequent reference in our columns. All candidates for the post should demand from this parish council satisfactory assurance concerning fixity of tenure, free annual holiday, and adequate salary.

THE HUGHLINGS JACKSON LECTURE OF THE NEUROLOGICAL SOCIETY.

THE Hughlings Jackson lecture of the Neurological Society of London for 1900 will be delivered by Professor Hitzig of Halle at 9 P.M. on Thursday, Nov. 29th, in the Theatre of the Examination Hall, Victoria Embankment, W.C., on "Hughlings Jackson and the Cortical Motor Centres in the light of Physiological Research." It will be remembered that this triennial lectureship was founded by the Neurological Society in honour of Dr. Hughlings Jackson, its first president, who also, three years ago, delivered the first Hughlings Jackson lecture. All members of the medical profession are invited to be present at the lecture which will be delivered in English.

OBSCURE CEREBRAL SYMPTOMS SIMULATING TUMOUR OF THE BRAIN AND ENDING FATALLY.

DR. A. ENGELHARDT of the Augusta Hospital in Cologne contributes to the *Munchener Medicinische Wochenschrift*, No. 36, 1900, an interesting case where the clinical symptoms pointed to an obscure cerebral lesion, presumably cerebral tumour, but where the necropsy revealed only a condition of degeneration of the optic tracts associated with profound anæmia. The importance of the case lies in the fact that owing to the uncertainty of diagnosis no attempt was made to carry out artificial feeding of the patient who had refused food during the last few weeks preceding death. The case was that of a young woman, aged 18 years, who was admitted to hospital on March 11th, 1897. Her family history was good and the patient's own personal history showed no serious illness. She had menstruated since the age of 13 years and suffered at times from headache and chlorosis. Latterly there were present disturbances of vision and temporary losses of eyesight, and ophthalmoscopic examination revealed the presence of optic neuritis. Syphilis could be wholly excluded, and it was concluded that a cerebral tumour was present. Her sight rapidly failed and a grey optic atrophy supervened with complete blindness. Headache was then severe, the urine was free from albumin and sugar, and as microscopic examination of the blood showed no anomaly except a simple anæmic condition (the hæmoglobin being 50 per cent. of the approval in all classes of the community, and we trust that it will not be forgotten among the earlier domestic measures of the new Parliament.

COMPLIMENTARY DINNER TO SIR GEORGE HARE PHILIPSON.

AT a meeting of the Southern Council of the Durham University Medical Graduates' Association held at the rooms of the Medical Society on Nov. 1st it was unanimously resolved to invite Sir George Hare Philipson to a complimentary dinner at the Café Royal, Regent-street, on Thursday, Nov. 29th. All graduates of the University who are members of the association in the south are invited to join in honouring the guest of the evening, who is one of the founders of the association and one of its strongest supporters. Full particulars may be obtained from the honorary secretary for the south, Dr. T. Outterson Wood, 40, Margaret-street, Cavendish-square, W.

DOWLING *v.* DODS.

TOWARDS the end of last June an action was brought by Miss Agnes Dowling, a nurse, against Mr. Louis Ferdinand Dods, a medical man, for libel. The circumstances were reported in THE LANCET, and may be remembered by our readers. The alleged libel was contained in a document purporting to be a certificate of lunacy and addressed to the local relieving officer. The defendant pleaded justification and privilege. The learned judge before whom the case was tried, Mr. Justice Darling, held that the occasion was privileged, but the jury found for the plaintiff, awarding her damages to the amount of £100. The plaintiff in her evidence showed herself to be the victim of dangerous hallucinations, so that the result of the trial surprised the medical profession and the public considerably, and a different issue upon appeal was anticipated. This week, before the Master of the Rolls, Lord Justice Collins, and Lord Justice Stirling, an application was made by Mr. Dods for judgment or a new trial. An attempt was made on Miss Dowling's part to show that Mr. Dods had been actuated by malice, but the judges held that there was no evidence of malice and judgment was entered for the defendant with costs. We congratulate Mr. Dods upon this result. We are satisfied that his conduct in the matter had its origin in a well-founded belief that Miss Dowling was of unsound mind and a source of danger to the community.

GENERAL PARALYSIS IN THE NAVY.

IN the November number of the *Edinburgh Medical Journal* Surgeon F. H. A. Clayton, R.N., assistant medical officer at the Royal Naval Hospital, Yarmouth, publishes an analysis of the statistics of general paralysis as observed in the Royal Naval Asylum for a series of years, and discusses the question of its etiology, with especial reference to sexual excess, syphilis, and alcoholism. An investigation of this disease as it occurs in the navy possesses the advantage that the inquiry is limited to a distinct class of men who are particularly subject to it, whose medical history since entry has been recorded, and whose physical condition, environment, and even mental characteristics are much alike. That seamen are more liable than officers to this disease appears from the fact that of 274 officers admitted in the last 25 years only 48 were paralytic cases, 12 of whom were warrant officers coming originally from the seamen class, whereas of 839 men 188 were paralytic cases. At present among 27 commissioned officers in the asylum there is no case, but, on the other hand, four out of six warrant officers and 18 out of 97 men come under that head. With respect to etiology Surgeon Clayton summarises his conclusions as follows: "Altogether, one inclines to accept the view that although syphilis or its toxins in many cases, by interference with nutrition, render liable to general paralysis many persons otherwise free, there is no evidence of direct connexion. The influences which act remotely are usually conditions tending to interference with nutrition and to promoting the growth of less highly organised tissues while the proximate influences probably act by lowering vitality. A 'specific' cause, as yet unknown, capable of developing the disease *per se*, though often aided by various factors, and which usually selects those apparently most healthy and vigorous both in mind and body, seems to be indicated by all the evidence." As is well known, general paralytics always become bed-ridden and in the concluding paragraphs of his article Surgeon Clayton gives some useful hints for the prevention of bed-sores.

HUXLEY MEMORIAL LECTURE.

To commemorate the anthropological work of the late Professor Huxley the council of the Anthropological Institute of Great Britain and Ireland has decided to found a public lecture, which will be called the "Huxley Memorial Lecture," and will be given annually at the opening of the winter session of the institute. The first Huxley Lecture will be delivered by the Right Hon. Lord Avebury, D.C.L., LL.D., F.R.S., and is announced to take place on Tuesday, Nov. 13th, at 8.30 P.M., in the Lecture Theatre of the Museum of Practical Geology in Jermyn-street, S.W., which as the scene of so much of Huxley's most impressive teaching, was felt to be the most appropriate place for such a ceremony, and has been placed for the occasion at the disposal of the Anthropological Institute. It is understood that Lord Avebury will take as the subject of his discourse Huxley's own contributions to anthropological science: a theme on which as a friend and colleague of Huxley, as himself a distinguished anthropologist, and as the first President of the Anthropological Institute he has peculiar authority to speak. Applications for tickets of admission should be addressed to the secretary, the Anthropological Institute, 3, Hanover-square, W., as early as possible.

DEATH UNDER NITROUS OXIDE.

A RECENT inquest held by Dr. Danford Thomas, the coroner for the county of London and Central Middlesex, upon a patient lately in the Great Northern Hospital, illustrates one of the few dangers which are incidental to the use of nitrous oxide. The patient, a man, aged 36 years, was admitted as an out-patient, declining to be taken as an in-patient, at the Great Northern Hospital. He was then suffering from suppuration in the structures of the neck. The swelling extended from the left ear round the jaw and well beyond the middle line. The left tonsil and structures between it and the outside were swollen and inflamed. As incisions were urgently called for the man was made to inhale nitrous oxide. This was given by one of the officers of the hospital who gave the gas diluted with air at first, but subsequently he employed pure nitrous oxide. An extremely small quantity of gas—a bag and a quarter—is said to have been inhaled and it is expressly stated that no re-breathing from the bag took place. When the ocular reflex was still present the incision was made and respiration ceased. It is said to have disappeared after the "excited stage." Possibly the man was never fully under the gas and the cessation of respiration was due to syncope from fear in the semi conscious condition. However, the house surgeon stated at the inquest that the death was due to asphyxia. At the necropsy œdema of the larynx was found to exist and the lungs were congested. Tracheotomy, which was performed as soon as the breathing failed, was unsuccessful and respiration never returned. These facts certainly point to heart failure as an element in the case. In all conditions in which the upper air passages are swollen and œdematous and respiration is hampered nitrous oxide is contra-indicated as it is liable to intensify the obstruction by promoting venous engorgement. That nitrous oxide is the safest of all known anæsthetics is now accepted on all hands, but as it is commonly given with little or no air there is a tendency to asphyxial complications, themselves not a necessary part of nitrous-oxide anæsthesia If there is a pathological state present in the patient these complications may become dangerous Again, incomplete anæsthesia under nitrous oxide is a source of peril. In it heart failure not infrequently occurs and has on several occasions proved fatal. The death was no doubt asphyxial in so far as the œdema of the glottis probably under the gas closed the air passages completely; but whether death would have occurred if the nitrous oxide factor could have been eliminated is, we think, a question open to argument. As we read the report it appears that either too much or too little of the anæsthetic was given. We are certainly imputing no blame, for such cases are extremely difficult to deal with and the judgment of even the most expert anæsthetist might lead him astray in his endeavour to do his best for his patient.

MARGARINE, WINE, AND TOMATOES.

MODERN adulteration is a fine art and there is little doubt that fraudulent practices often escape detection. Any proposal, therefore, to make detection more certain must be very carefully considered. Some time ago it was suggested that margarine should be compulsorily coloured in order that it may be distinguished from the yellow colouring of butter. Of course, if margarine manufacturers were compelled to make their margarine blue or pink there could be no possibility of mistaking this substitute for butter. A better proposal, however, would appear to be that of adding an infinitesimal proportion of phenol phthalein to margarine, which would give the margarine no colour at all until it were made alkaline by adding soda to it, when it would turn a brilliant carmine. The question remained to be answered, however, as to whether the presence of such a minute amount of coal-tar derivative would be injurious. It has recently been ascertained that even large quantities of phenol phthalein are quite harmless and produce no unpleasant symptoms whatever. This device could be applied to a number of food substitutes, the recognition of which as such would thereby be much facilitated It is well known that low-class wines are frequently worked up from the residue of crushed grapes after the bulk of the juice has been expressed. Such wine, which is known as marc wine, may or may not be wholesome. It is certain to be of feeble quality. At any rate, it is desirable that the detection of such wine should be easy. Phenol phthalein added in the proportion of 1 part to 100,000 of wine would not make the wine a bit more unwholesome, whilst the addition of alkali to the wine would result in a brilliant red colour which would brand at once its origin. Injury to health may obviously arise by the consumption of unsound or unripe articles of food, and the worst form of fraud is that in which a colouring or preservative agent is used to conceal bad characteristics It would appear, for example, that tomatoes are cunningly coloured in order to make them look attractive and ripe The danger of consuming these articles is great, for it is well known that unripe and unsound food is constantly a source of diarrhœa and other serious disturbances. This proceeding is not justified by the fact of the colouring matters being possibly innocuous. Amongst the colours so employed are the coal-tar colours and cochineal, both of which may be detected by certain chemical tests. The tomatoes generally coloured are those which are preserved. It is well that the whole subject of the artificial colouring and preservation of food is receiving the attention of a Departmental Committee, whose labours we hope will shortly be finished, and whose pronouncement, we trust, will give power to exercise a greater control over this form of tampering with food.

A PARISH MEDICAL OFFICER FOR SOUTH UIST.

IN our issue of Oct. 20th there appeared an advertisement for a medical officer for the parish of South Uist (Northern Division) We do not desire to put obstacles in the way of South Uist obtaining a competent medical officer; it is an isolated parish and its medical officer will have great responsibilities; but though we have inserted the advertisement we think it our duty to remind all candidates that the Parish Council of South Uist was responsible for the scandalous treatment of Mr. J. Lamont to which we have made frequent reference in our columns. All candidates for the post should demand from this parish council satisfactory assurance concerning fixity of tenure, free annual holiday, and adequate salary.

THE HUGHLINGS JACKSON LECTURE OF THE NEUROLOGICAL SOCIETY.

THE Hughlings Jackson lecture of the Neurological Society of London for 1900 will be delivered by Professor Hitzig of Halle at 9 P.M. on Thursday, Nov. 29th, in the Theatre of the Examination Hall, Victoria Embankment, W.C., on "Hughlings Jackson and the Cortical Motor Centres in the light of Physiological Research." It will be remembered that this triennial lectureship was founded by the Neurological Society in honour of Dr. Hughlings Jackson, its first president, who also, three years ago, delivered the first Hughlings Jackson lecture. All members of the medical profession are invited to be present at the lecture which will be delivered in English.

OBSCURE CEREBRAL SYMPTOMS SIMULATING TUMOUR OF THE BRAIN AND ENDING FATALLY.

DR. A. ENGELHARDT of the Augusta Hospital in Cologne contributes to the *Münchener Medicinische Wochenschrift*, No. 36, 1900, an interesting case where the clinical symptoms pointed to an obscure cerebral lesion, presumably cerebral tumour, but where the necropsy revealed only a condition of degeneration of the optic tracts associated with profound anæmia. The importance of the case lies in the fact that owing to the uncertainty of diagnosis no attempt was made to carry out artificial feeding of the patient who had refused food during the last few weeks preceding death. The case was that of a young woman, aged 18 years, who was admitted to hospital on March 11th, 1897. Her family history was good and the patient's own personal history showed no serious illness. She had menstruated since the age of 13 years and suffered at times from headache and chlorosis. Latterly there were present disturbances of vision and temporary losses of eyesight, and ophthalmoscopic examination revealed the presence of optic neuritis. Syphilis could be wholly excluded, and it was concluded that a cerebral tumour was present. Her sight rapidly failed and a grey optic atrophy supervened with complete blindness. Headache was then severe, the urine was free from albumin and sugar, and as microscopic examination of the blood showed no anomaly except a simple anæmic condition (the hæmoglobin being 50 per cent. of the normal) the diagnosis of cerebral tumour was rendered probable. The knee-jerks were abnormal, the right being excessive and the left being diminished. She gradually grew feeble and paralysed and the sense of smell seemed entirely to have disappeared, while epileptiform convulsions now developed. A right-sided hemianæsthesia was noted. The rectal and vesical functions were retained. Her appetite was lost and she refused food and began to get emaciated, but this being regarded as due to a growing cerebral tumour no attempt was made at artificial feeding. The patient died in a condition of inanition on March 17th, 1898. The necropsy revealed a condition of optic atrophy, with degenerated fibres (staining black with Marchi's method) in both optic nerves and tracts. No cerebral tumour was found, but the brain appeared very pale and anæmic and unusually dry. The condition was in fact one of profound anæmia with secondary cerebral symptoms, so closely simulating those of tumour, however, that no treatment was directed towards the real disease to which the patient succumbed.

DRY DISINFECTION OF THE HANDS.

IN a recent annotation[1] we mentioned some methods of disinfecting the hands. Yet another method is that devised by Dr. Vollbrecht and described by him in the *Archiv fur Klinische Chirurgie*, 1900, p. 554, the detergent medium in this case being a kind of solidified emulsion of soap and alcohol. The mode of preparation seems simple. 60 grammes of good "almond" soap having been scraped into a mortar standing in a hot-water bath enough alcohol at 97° is added to dissolve it. As soon as the solution has taken place the remainder of the alcohol (one litre in all) is added and the whole is then allowed to stand until the contents of the mortar have become solid. The product having been cut into cakes should then be wrapped in tin-foil and stored for use. 35 grammes (about one and a quarter ounces) of the soap (price two centimes) are enough for one detergent operation, and as the melting point is 110° F. it can be carried in the pocket. The process of disinfection is thus described. The soap having been carefully spread over the hands should be rubbed in vigorously with a sterilised brush during five minutes. The alcohol gradually evaporates but the amount of soap left behind is not enough to make the hands feel greasy or to interfere with the handling of instruments. No lather is produced unless water be added. The texture of the skin is in no wise injured by the soap which, on the contrary, preserves and renders it soft. According to the inventor, who describes an elaborate system of testing, the results from the point of view of disinfection are quite equal to those obtained by the Mikulicz method. If need be the soap can be used for sterilising instruments by heat as it is readily inflammable.

THE QUESTION OF THE COMMUNION CUP.

WE are glad to see that the question of the danger of infection which arises from the use of a common chalice at the administration of the Holy Sacrament, to which reference was made in THE LANCET of Oct. 13th (p. 1088), has been taken up by our ecclesiastical and other contemporaries. The *Church Times*, the *Guardian*, the *Pilot*, and the *Record* have all referred to the matter. The *Guardian* suggests that a committee of Convocation which might select physicians as assessors might "profitably consider the point"; the *Church Times*, in its leading columns, suggests simply the appointment by the bishops of a commission of inquiry upon which medical men might serve, to be followed by a commission of liturgical experts; and the *Pilot* says: "If medical science proves that the danger is more general than was formerly supposed the Church must be prepared to advance *pari passu* to greater precaution." Whatever the constitution of the inquiring body may be we hope that the authorities of the Church will not delay to take the matter into consideration. Instances of latitude from the strict letter of the Prayer Book as formulated some 300 years ago have already received the sanction of more than one of the bishops and if the times are not ripe for a revision of the Book of Common Prayer we may yet hope to see the Ordinaries of the respective dioceses giving directions to their clergy by means of which the weaker brethren may be saved from offence. A somewhat similar question arose in the Roman Communion not so very long ago with reference to infection by the use of common holy water stoups. An ingenious delivering apparatus was invented by Mr. J. J. Bruns of Arnhem[1] to overcome this difficulty and this apparatus was submitted to the Archbishop of Utrecht and approved by him. There are always those who delight in putting difficulties in the way of reforms, but we cannot but hope that in this matter the importance of the question may serve to emphasise the need for its thorough consideration.

THE SOCIETY OF APOTHECARIES OF LONDON: THE TITLE OF LICENTIATES.

SINCE the resolution of the Court of Assistants of June 19th, 1900, was communicated to the medical journals constant applications have been made by Licentiates in reference to the titles which they may adopt and suggestions have been offered as to particular letters and signs descriptive of the qualification of L.S.A. 1886. By a further resolution of the Court of Assistants of Oct. 8th it has been resolved that the only titles which the Society can authorise as a proper description of the qualification L.S.A. 1886 are those of Physician and Surgeon, either added to the title of L.S.A. 1886 or used alone. And it was further resolved that the Society should discourage in every possible way the use of any other titles or letters on the ground of its tending to cause confusion and to destroy uniformity. The clerk of the Society, Mr. J. R. Upton, from whom we obtained this information, adds that the Society trusts that its Licentiates will coöperate in adopting a course which, it is believed, will prove beneficial to themselves.

MR. MANSERGH ON WATER-SUPPLY.

THE inaugural address to the Institution of Civil Engineers was delivered by Mr. James Mansergh on Tuesday, Nov. 6th. It appears from the abstract published in the *Times* that the speaker in the course of his remarks covered a great deal of ground and expressed with some freedom his views on potable water. An idea may be obtained of the variety of the matter brought under review when we say that the orator quoted largely from an American translation of the well-known work of Frontinus on the water-supply of ancient Rome and from the Transactions of the Society for Psychical Research on the question of "water-finders." These interesting matters are of less importance to medical men than are questions concerning the purity of the water that we drink. And on this subject Mr. Mansergh may be considered an authority, for he was a member of the Balfour Commission which was appointed to investigate the quantity and quality of the metropolitan water-supply. Mr. Mansergh's views on pathogenic organisms, according to the *Times* report, are as follows:—

> "We were" he said, "still groping in the dark as to the work these ubiquitous micro-organisms were designed to do in the economy of nature. Might it not be wiser to assume the majority of them to be actively beneficent instead of being simply harmless? In removing from the water drunk in London 98 per cent. of those found in the river in order to capture a stray typhosus or Löffler's bacillus (neither of

---

[1] Ps. xci.

[1] THE LANCET, Jan. 27th, 1900, (p. 252).

which had ever been found in the raw water) might we not be doing harm rather than good? Still this pessimistic view need not trouble us much, for health statistics proved that the risk of harm arising either from the presence in the water of so-called pathogenic organisms or from the removal *of the harmless ones was so small that it might be calmly* disregarded."

These comfortable words of Mr. Mansergh with regard to pathogenic germs were followed by a warning as to the danger which may be apprehended from water derived from sources hitherto considered pure. "A word of warning might, however, be said about water obtained from elevated and sparsely-populated moorlands, for," he said, "the danger was greater if such water became infected, especially if not passed into impounding reservoirs, than if the supply were taken from a large river." We hope that the members of the Institute of Civil Engineers and the distinguished guests passed a pleasant evening and returned home reassured by the fact that the water of London with its pathogenic germs which can be calmly disregarded is still derived chiefly from the Thames and the Lea, uncontaminated with any water from "sparsely-populated *moorlands*"—*the* "*pure nectar from Wales*," as it was characterised by Lord Llandaff.

THE USE OF TOBACCO ON ACTIVE SERVICE.

THE war in South Africa has taught many things of greater and *of less importance. Perhaps nothing that it has* demonstrated has been more marked than the important part which tobacco plays in the soldier's existence. Whether this is to be reckoned as a great fact or a small one there can be no doubt about the truth of it. Yet the Duke of Wellington's armies had no tobacco worth speaking of. If they did not forbid its use, at any rate the Iron Duke's officers were directed to advise their men strongly against it. What a curious contrast with the campaigning in South Africa, where marches and privations as long and as stern as any suffered by our great-grandfathers were borne by the volunteers and soldiers of to-day with a grumble only when their "smokes" failed them. We have it from many who took part in the forced marches leading to Paardeberg, to Bloemfontein, to Pretoria, and beyond, that when rations were but two or three biscuits a-day the only real physical content of each 24 hours came with the pipe smoked by the smouldering embers of a camp fire. This pipe eased the way to sleep that might otherwise have lingered, delayed by the sheer bodily fatigue and mental restlessness caused by *prolonged* and *monotonous exertion. It is difficult, then, to* believe that tobacco is anything but a real help to men who are suffering long labours and receiving little food, and probably the way in which it helps *is* by quieting cerebration—for no one doubts its sedative qualities—and thus allowing more easily sleep which is so all-important when semi-starvation has to be endured. The cases of acute mental derangement in the course of campaigns such as the present are many. There have indeed been many in South Africa. It would be most profitable and interesting could medical officers have taken special note of the capacity for sleep previously evidenced by those who broke down and also of their indulgence or non-indulgence in tobacco. We are inclined to believe that, used with due moderation, tobacco is of value second only to food itself when long privations and exertions are to be endured. Two features are to be noted with regard to the smoking practised on active service. It is almost entirely in the open air and it is largely on an empty stomach. The former is always an advantage; the latter we generally reckon a most unfavourable condition. Shall we see in the near future patients with tobacco amblyopia or smoker's heart acquired while the trusting friend of tobacco thought that he was enjoying unharmed the well-earned solace of a hard day's march? We believe not, and that the open air will have saved what might have been the untoward results of smoking when unfed.

MEETING OF THE GENERAL MEDICAL COUNCIL.

SUMMONSES have been issued for a meeting of the General Medical Council on Tuesday, Nov. 27th, at 2 P.M. *The Penal Cases Committee will* meet on the preceding Saturday and the Executive Committee on Monday, Nov. 26th.

THE INSPECTION OF CONVENTS.

A LETTER which appeared in the *Times* of Nov. 5th raises a most important point. We are not among those who consider that convents are dens of iniquity, that the bricking up of recalcitrant nuns is of daily occurrence, or that excavations in the back-gardens of convents would reveal facts such as those which horrified the pious inhabitants of Cologne when, in 1106, they dug anew the foundations of their walls and came across the bones of the 11,000 virgins and others. But the correspondent to whose letter we refer mentions facts, which so far have not been denied, which reveal a most dangerous state of things. The doors (of the convent to which the writer refers) into the street are *locked at night and the keys are handed over to the reverend* mother, there being no means of exit until she is communicated with. An outbreak of fire occurred which fortunately did not end in disaster; but how easily it might have done so. To our minds, as regards sanitary and hygienic conditions, the palace, the ordinary dwelling-house, the convent, and the tenement house should all be under the same regulations. Epidemics and fire are no respecters of persons or of religious communities, and though the promise of angelic protection still holds good, yet it was only given to those in a way[1]—namely, in a definitely marked out path, a point which the Devil omitted when he quoted the passage for his own purpose. Not to use means which have been provided for our safety is universally recognised as demanding that punishment which is allotted for those who tempt God. True, there must be discipline, but discipline must not be such as to combine presumption.

THE annual dinner of the Aberdeen University Club, London, will be held at the Trocadéro Restaurant on Wednesday, Nov. 21st, at 7 P.M. Sir William McGregor, K.C.M.G., Governor of Lagos, will take the chair, and members intending to dine should communicate with the honorary secretaries, Mr. J. A. Robson and Dr. James Galloway, at 54, Harley-street, W.

DR. JOSEPH PRIESTLEY, medical officer of health of Lambeth, who was recently selected by the Municipality of Bombay for the appointment of Executive Health Officer to the City of Bombay, has not seen his way to accept the position. The borough of Lambeth is to be congratulated upon retaining the services of Dr. Priestley.

MR. HUTCHINSON, F R S, has offered, and his offer has been accepted, to build and fit out an educational museum in connexion with the Friends' School at Ackworth, near Pontefract, Yorkshire. Museums on similar lines have been provided by Mr. Hutchinson's generosity at Haslemere, Surrey, and at his native town, Selby, Yorkshire.

PROFESSOR A. H. YOUNG, M.B. Edin., F.R.C.S. Eng., has been appointed Representative of the Victoria University for five years on the General Medical Council in succession to the late Dr. D. J. Leech.

PROFESSOR CALMETTE ON PLAGUE.

PROFESSOR A. CALMETTE, Director of the Pasteur Institute at Lille, in the course of the first Harben Lecture of the Royal Institute of Public Health, delivered at the Examination Hall of the Royal Colleges of Physicians of London and Surgeons of England on Nov. 7th, said that the recent appearance of plague at Glasgow had decided him to choose the study of this disease as the subject of his lectures. Plague now menaced all the maritime nations of the globe and it had become necessary to take rigorous measures to stop its extension. The progress of hygiene and the knowledge acquired during the last five years on the etiology, treatment, and prophylaxis of the affection enabled it to be combated very efficaciously and its centres to be rapidly circumscribed. It was known that the plague bacillus was found in the buboes and sputa of the patient, that it was also frequently found in the blood, that it had the form of a short bacterium, slightly ovoid, that it was easy to stain by the ordinary laboratory methods, and that it could be cultivated on the usual media.

From a clinical point of view the plague assumed two clinical forms—bubonic plague and plague without buboes, the former being more commonly observed. Persons attacked by bubonic plague ordinarily suffered at the commencement of the illness from a sensation of great weakness with heaviness of the head and painful pricking or tingling at the place where the buboes would appear. The patient was suddenly taken with repeated shivering, of short duration at first but getting longer and longer. Intense pain, great thirst, alimentary or bilious vomiting, and diarrhœa afterwards occurred. Glandular congestion, ordinarily limited to a single group of glands, appeared on the same day or on the day after. A bubo appeared with little delay; it was accompanied by a painful tumefaction, the least pressure on which caused the patient to cry out. The temperature rose very quickly, the pulse was rapid, full, often dicrotic, but regular, and the breathing was quickened. The facies was typical: red, haggard, weeping eyes with an expression of agony and terror, and the tongue dried, furred, and red at the edges and point. Sometimes at the commencement the patients, after a short period of excitation and mad terror, were smitten suddenly with an overpowering somnolence and collapse; they then resembled subjects struck with serious adynamic typhoid fever. The head was thrown back, the eyelids were half closed, the mouth was slightly open. When they were spoken to in a loud voice they looked around with a stupefied expression, replied with much difficulty, and dragged their words like intoxicated persons. When exciting phenomena dominated them the patients suffered from hallucinations of sight or hearing, believing themselves to be surrounded by extraordinary animals, as in alcoholic delirium. Sometimes they showed very clear symptoms of meningitis, opisthotonos, converging strabismus, dilatation of the pupils, delirium, cramp of the arms, flexion of the legs, and fibrillary movements of the muscles of the face. The localisation of the glandular lesions determined the special attitude of the patients. The least movement caused them to shriek; the skin was frequently covered with petechiæ; in grave cases turbid sero-sanguineous pustules formed. or even actual carbuncles, which latter characterised the special type to which ancient authors gave the name of "black plague." On auscultation signs were constantly found after the third or fourth day of broncho-pneumonia. The cough was dry and painful, terminated by the expectoration of frothy sputa, slightly viscid, yet streaked with blood and containing the plague bacilli in great quantities. In grave cases the heart presented signs of an alteration of the myocardium, with prolongation of the first sound and other cardiac symptoms. In these grave cases the patients scarcely micturated at all and the urine, at times containing blood, was very acid and albuminous. Except in entirely benign cases, suppuration of the buboes was the rule and was generally of good augury, as it indicated that the system was defending itself against the plague infection and that the infection remained localised. Convalescence was always long. The forms of plague without buboes and without apparent glandular congestion were much rarer than the forms of classical bubonic plague which he had just described. The primary pneumonic plague resulted from the penetration of the microbe into the respiratory channels and it was to this exceedingly grave form that Dr. Müller and his laboratory assistants succumbed in 1898 at Vienna. Another and still rarer form of plague without buboes was plague septicæmia or pesticæmia which developed with extreme rapidity and was caused by the intense pullulation of the plague bacillus in the blood and in the organs. It was not exactly known where the virus first effected an entrance in these cases; perhaps the microbe penetrated by the intestine or directly into the blood through some little open sore or cut. Post-mortem examinations of patients who had succumbed to this particularly severe form showed very congested mesenteric and retro-peritoneal glands of a characteristic purplish colour like dregs of wine, which fact seemed to support the hypothesis of penetration of the virus by the gastro-intestinal channels. When the plague was studied in an epidemic centre all the forms above described were found, but it sometimes happened that the first cases did not present clear characteristics and it was thus possible that they might be incorrectly diagnosed. At Calcutta Dr. Simpson and Dr. Cobb reported the presence of the plague bacillus in cases of inguinal glandular congestion which had been noticed with extraordinary frequency among the men of a certain regiment stationed at Hong Kong during the epidemic of 1894. An official Commission appointed to investigate the evidence of Dr. Simpson and Dr. Cobb declared that they were cases of simple non-venereal buboes. In reality the commission was wrong. It was dealing with an exhausted nonmalignant form of plague that ancient writers had already recorded under the name of *pestis mitior*, as frequent at the commencement and the end of great epidemics. Such facts proved how little the best clinical examination alone could suffice to make a diagnosis of plague. Such diagnosis could only be determined when the bacteriological examination demonstrated the presence of the microbe of Yersin in the glandular fluid in the blood or in the sputum. At the commencement of a case of bubonic plague, in order to ascertain whether the plague microbe was present or not, it might be feared that to make a puncture with Pravaz's syringe right into the lymphatic tissues to extract therefrom some drops of fluid to be fertilised in the usual manner and examined immediately after colouration would spread the infectious germs beyond the glands in which they had been localised. But to-day with the aid of sero therapy there was no foundation for that fear, because to put the patient beyond the danger of any possible reinfection it was only necessary, directly after the puncture with Pravaz's syringe, to inject a small quantity (about five cubic centimetres) of anti-plague serum into the middle of the gland or at a short distance from it. The extracted fluid should be placed immediately in tubes of nutritive gelose and in tubes of bouillon of beef or of veal at a temperature of from 25° to 30° C. for a period of 24 hours. At the same time a small quantity should be spread out on glass slides coloured with methylene blue or thionin. On gelose the appearance of the microbe colonies did not present any very specific characteristics, but their number indicated the degree of gravity of the infection. In the meat bouillon the specific characteristics were more precise. The bouillon remained clear and transparent and contained some slight whitish clots floating on the surface, which sank to the bottom of the tube at the least movement. If the bouillon was turbid it was evident that some microbe other than the plague bacillus, perhaps of a mixed infection, was present. In such circumstances the diagnosis should be made more precise by inoculating susceptible animals with the culture. The mouse especially took the plague and it was only necessary to prick this little animal in the thigh with a needle dipped in the culture on gelose in order to give it the disease and cause its death in from 36 to 48 hours. When the inoculated animals succumbed very characteristic lesions were found on the bodies and the plague bacilli were in great quantities in all the organs, especially in the glands, the spleen, and the liver. To diagnose a case of suspected pneumonic plague it was necessary to collect as much as possible of the rusty sputum, to dilute it with a small quantity of boiled water, and to fertilise several tubes of gelose with platinum wire, the temperature not exceeding from 20° to 23° C. At this relatively low temperature the pneumococci did not germinate, the streptococci germinated badly and very slowly, while the plague bacilli developed rapidly. At the end of two or three days the plague colonies were very numerous. They must then be examined and transferred to fresh gelose tubes in order to get them in a pure state.

THE TWENTY-NINTH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD (1899-1900).

A SOMEWHAT melancholy feature of the annual report of the Local Government Board this year, which was issued last week, is the record of the fact that since the last report was issued death has overtaken no less than six of the important officers of the staff. Towards the close of the official year ending March 31st, 1900, Sir Richard Thorne Thorne, K.C.B., F.R.S., the medical officer, died after a brief illness, and the opportunity is taken in the present report of placing on record the sense of the staff of the Local Government Board "of his eminent services in relation to the public health and of the loss which the country has sustained by his death." The Local Government Board also have to regret the loss through death during the year of the services of Major-General A. de Courcy Scott, R.E., as examiner under the Metropolis Water Acts, and of Professor Sir Edward Frankland, K.C.B., F.R.S., as water analyst. Mr. Charles Perrin, M.I.C.E., has succeeded Major-General Scott as water examiner and the duties performed by Sir Edward Frankland are now carried out at the Government Laboratory under the superintendence of Dr T. E. Thorpe, F.R.S.

In some respects it may be taken, therefore, that death, which has been so conspicuously busy in this State department, accounts for the incompleteness of certain sections of the report. Mr. Perrin, in his report, for example, on the metropolitan water-supply, deemed it desirable "to compile a report in the usual form with a view to maintaining continuity in the statistical information available for future reference." As he admits, this information could not in any degree be based on personal knowledge of the incidents of the year, but has been compiled from facts already on record and "from information kindly supplied by the officers of the water companies." Similarly the chemical examination of the metropolitan water-supply lacks continuity. The reports for the first seven months of the year were made by the late Sir Edward Frankland, those for August and September were made by Dr. Percy Frankland, F.R.S., and those for the rest of the year by Dr. T. E. Thorpe. Under these circumstances no general report could be made, but a memorandum based on the monthly reports was prepared in the department. The diagrams thus compiled are not complete and a note at the bottom states that the Board do not possess the information necessary (in some respects) to complete the table (or tables) with regard to the months of October, November, and December. There are no bacteriological records at all and the quality of the London water-supply according to chemical examination is not referred to in the synopsis. Mr. Perrin reports, however, in regard to filtration that the year 1899 was on the whole favourable for the operations of the companies supplied from the Thames and Lea, the Thames water being in good condition during 314 days, moderately discoloured and turbid during 40 days, and exceptionally muddy and turbid on only 11 days of the year.

In regard to the working of the Food and Drugs Act it appears that the number of samples secured for analysis is steadily increasing and with this increase, as might be expected, there is a reduction in the percentage of the samples reported against. In some districts still there were no samples taken. The proportion of samples taken in 1899 was two per 1000 of the population. The interesting and important observation is made that in the large number of districts where the proportion of samples taken did not reach three per 1000 of the population the samples reported against averaged 10·1 per cent.; in those where the proportion taken was between three and four per 1000 the adulterated samples were 8·7 per cent.; while in the districts where samples were taken at the rate of over four per 1000 the rate of adulteration fell to 7·5 per cent. These results surely justify the opinion of the Select Committee on Food Products Adulteration, 1894-96 that a proportion of samples much in excess of one per 1000 of the population should each year be taken for analysis in the district of every local authority. The proportion of adulterated samples was slightly higher this official year than last year, the figures being respectively 8·7 and 9·4 per cent. Milk was adulterated to the extent of 10·5 per cent. of 21,964 samples examined, which is an increase on the previous year. Three or four years ago London had shown an improvement in its rate of milk adulteration but the percentage, which had been 14·6 in 1897 and 12·9 in 1898, rose in 1899 to 15·4. Only nine of the "32 great towns" of the Registrar-General's weekly returns had a more unsatisfactory rate of milk adulteration than London in 1899. The percentage of adulteration of drugs was greater than that of food, no less than 17·8 per cent. being classed as adulterated. Nearly one-fifth, however, of the samples taken were of camphorated oil and camphor liniment, of which 28 per cent. were condemned generally because of a deficiency in the proportion of camphor present but sometimes because (in addition) mineral oil was substituted for the olive oil prescribed by the British Pharmacopœia.

A large sum of money represented in loans to the joint Boards has been sanctioned in respect of systems of sewerage and sewage disposal, the provision of waterworks and of cemeteries, the provision and equipment of hospitals, and the purchase of land in connexion with those objects. Many applications have been made to the Board for sanction to loans for the execution of works of sewage disposal involving the adoption of the bacterial processes. In view of the fact that a Royal Commission is inquiring into the subject it is interesting to hear the decision of the Local Government Board on this question of loans to be devoted to new processes of sewage disposal which are thus *sub judice*. Although these processes, it is stated, must in many respects be regarded as in the experimental stage the Local Government Board have not declined to consider these applications where the process was to be supplemented by land treatment of the effluent from the bacterial filters. In each case, however, a local inquiry has been held and full evidence has been required to show that the process contemplated is likely to prove of considerable assistance in the purification of the sewage. Where such loans have been sanctioned it has been the usual practice of the Board to require an undertaking from the local authority that, in the event of the method adopted not proving satisfactory some other approved method of sewage disposal would be substituted.

The returns relating to the new by-laws and regulations under the Public Health Acts afford evidence of continued activity on the part of local authorities in making by-laws on the more important matters—such as scavenging, the prevention of nuisances, the regulation of offensive trades, the regulation of common lodging-houses, and the construction of buildings.

As to vaccination returns, these will be published *in extenso* in the report of the medical officer for the year 1899-1900 which will appear as a supplement to the present volume and will contain information as to some of the inspections which are only briefly referred to in the present report, as well as to other sanitary questions which have specially engaged the attention of the medical staff during the year.

In regard to the control of the manufacture of alkali and chemicals it appears that the supervision exercised by the staff of special inspectors continues to be attended with good result. On the whole, however, there has been a slight increase in the proportion of nuisances arising from chemical trades which may be referred perhaps to the extra strain put upon the manufacturing plant in consequence of the satisfactory expansion of general trade. Numerous chemical businesses have been supervised, and care appears to be taken as far as possible to utilise such improvements as the growth of scientific knowledge suggests with the view of preventing nuisance from the discharge into the atmosphere of deleterious chemical compounds.

It is interesting to notice that pauperism steadily declines and that during the last official year it reached the lowest figure on record. Again, the report, referring to the returns of deaths from starvation, states than in few instances was death ascribed solely to want of sufficient or proper food. For the most part the deaths appear to have been due to disease consequent upon, or accelerated by, want or exposure, or both, and in some instances to self-neglect. Complaints are made in respect to the sick-wards of certain workhouses which are said to be structurally very bad as well as bad from a sanitary standpoint, comparing most disadvantageously with hospitals erected by voluntary movement and organisation.

The report teems with the usual statistics in regard to the relief of the poor and the poor-rate, and local taxation and valuation.

Obituary.

WILLIAM ANDERSON, F.R.C.S. ENG., L.R.C.P. LOND.,

SURGEON TO ST. THOMAS'S HOSPITAL; PROFESSOR OF ANATOMY TO THE ROYAL ACADEMY OF ARTS.

WILLIAM ANDERSON was born on Dec. 18th, 1842, in London—as he used to say, within the sound of Bow bells. He was educated at the City of London School. On leaving school he did not immediately enter on the study of medicine, but became an art student at the Lambeth School of Art. There he attained considerable proficiency as a draughtsman and acquired an interest in art which he retained through the whole of his life and which was a great source of pleasure to him besides being useful in his anatomical teaching. In 1864 he entered St. Thomas's Hospital where he obtained college prizes in three successive years, and in 1867 carried off the Cheselden medal—the highest prize in surgery. He obtained the qualifications of M.R.C.S. Eng., and L.S.A. in 1867, that of L.R.C.P. Lond., in 1868, and in 1869 became Fellow of the College of Surgeons. After qualifying, Anderson was for a time house surgeon at the General Infirmary, Derby, but returned to St. Thomas's Hospital, where he was appointed surgical registrar and demonstrator of anatomy on the opening of the new hospital in 1871. As a demonstrator of anatomy he was a popular and indefatigable teacher till an event occurred which altered for a time the whole course of his life. The Japanese Government having founded a Naval Medical College at Tokio wished to place an English surgeon at its head. The selection was intrusted to some eminent members of the profession in London, by whom Anderson was appointed, not without competition. He sailed in 1873 with his newly-married wife to take up his duties and remained in Japan nearly seven years.

With the position of Director of the Naval Medical College Anderson had to combine the duties of an almost universal professor. He lectured on anatomy, physiology, and surgery, and presumably on medicine also. In his earlier lectures he had the assistance of an interpreter, a Japanese student who knew English and translated his lectures orally, but afterwards (how soon we cannot say) he lectured in Japanese. Few Europeans it is said acquired the language more rapidly or spoke it more accurately. His lectures, judging from the reports of some students who afterwards came over to England, were highly valued by his Japanese pupils, some of whom became deeply attached to him. The position was in many ways a very pleasant one to Anderson. His unprejudiced and genial nature rapidly adapted itself to its new surroundings. He lived on intimate terms with the diplomatic circle and the English colony and became acquainted with Japanese life also. Soon after his arrival he was appointed medical officer to the English Legation at Tokio.

In one respect especially his residence in Japan was fortunate as giving him a rare opportunity for the exercise of his critical knowledge of works of art. His early art education had given him the tastes not only of an artist but of a collector. Indeed, he took out with him to Japan a small collection of old engravings, etchings, and illustrated books of anatomy, in which he took great delight. This collection was, however, swept away by a fire, from which he himself, his wife, and infant child escaped with little more than such clothes as they had on, and a valued microscope, the parting present of his students at St. Thomas's Hospital, which was snatched from the flames by a faithful domestic. The same calamity occurred a second time, but Anderson more than made up his losses by his valuable collections of Japanese art. Most foreigners collected curios, and no doubt at that time got them there on much easier terms than in the present day. But Anderson did more than amass a miscellaneous collection of beautiful objects. He made a serious study of the history of Japanese pictorial art; and with his practised eye and good judgment was able to collect a series of drawings and paintings of different periods which is said to have been in some respects unequalled and which was more carefully housed than his earlier collection.

In 1880 a vacancy occurred at St. Thomas's Hospital owing to the much regretted retirement through ill health of Mr. W. W. Wagstaffe, and it was resolved to invite Anderson back to take the place of assistant surgeon and joint lecturer on anatomy. He thus re-joined his old hospital and again was highly valued as a teacher. In teaching anatomy he had one advantage which it is not given to all anatomists to possess—namely, his power of drawing. His sketches on the blackboard were the wonder of his pupils. Beginning with a bold but unerring outline he would gradually fill in the details till a finished picture, more instructive than a ready-made diagram, was before the class. The same power he displayed, and before more critical spectators, when lecturing on anatomy to the Royal Academy.

The course of Anderson's life at St. Thomas's Hospital much like that of other hospital surgeons. From assistant surgeon he became full surgeon in 1891, having in 1887 added to his general work the charge of the Department for Diseases of the Skin, a subject in which he took much interest; but he never gave up teaching anatomy till he was appointed in 1898 joint lecturer on surgery. He belonged to no other hospital or school and all his professional interests were connected with St. Thomas's Hospital. In one other capacity he was, however, very active—namely, as an examiner. In the Royal College of Surgeons of England he was examiner in surgery for the Conjoint Board and held this office up to the time of his death. Indeed, he was examining during the last week of his life. He was also examiner in surgery for five years in the University of London.

Anderson was interested in the history of surgery and especially in the application of fine art to its illustration. He wrote a paper, excellently illustrated, on "Art in Relation to Medical Science" in the fifteenth volume of the St. Thomas's Hospital Reports, which is the best sketch of that subject accessible in the English language. An interesting lecture on the "History of Surgery since the Middle Ages" in the eighteenth volume of the same Reports should also be mentioned. His strictly surgical papers were not very numerous, but he published in 1896 a work on Deformities of the Fingers and Toes and contributed three articles to "Heath's Dictionary of Surgery." He wrote also the section on the Genito-Urinary Organs in "Morris's Treatise on Anatomy," and contributed several surgical papers to the St. Thomas's Hospital Reports, THE LANCET, *British Medical Journal*, &c. In the "Nomenclature of Diseases," published by the Royal College of Physicians of London in 1896, he wrote, in conjunction with Mr. Shattock, the section on Malformations, a laborious and recondite piece of work.

No account of Anderson's career would be complete without reference to his work in connexion with the fine arts. When he was appointed, in succession to the late Professor Marshall, professor of anatomy to the Royal Academy it was generally recognised that by his knowledge of art and anatomy alike he was a worthy successor of the eminent men who have filled that chair. But it was chiefly in connexion with Japanese art that his name was known. When the greater part of his collection of Japanese pictures and drawings was bought for the British Museum and exhibited in the gallery of the Print Department it attracted general attention among connoisseurs, both English and continental. The general judgment was that, even if some more brilliant and costly specimens might be found elsewhere, no collection so important historically had ever been brought together in Europe, and possibly not even in Japan itself. His "Descriptive and Historical Catalogue" became an authority on the subject. Anderson was still better known by his splendid work on "The Pictorial Arts of Japan," in two folio volumes, published in 1886. He also wrote a monograph on "Japanese Wood Engraving" in 1895. Anderson kept up his interest in Japanese matters other than artistic and was one of the most active founders of "The Japan Society," of which he was at one time president. He was well known to, and highly esteemed by, the Japanese colony in London, and received from the Japanese Government the distinction of "Commander of the Order of the Rising Sun."

In the various circles in which he moved, medical, artistic, and Japanese, Anderson's wide knowledge, unaffected geniality, and modesty made him an attractive personality, but naturally of a retiring disposition he did not go much into society. In all professional relations he was esteemed for his sincerity and thoroughness and for the strict conscientiousness with which he fulfilled all duties devolving upon him. Whether in the dissecting room or in a tedious examination, or in going through a long list of operations, he never allowed himself to be tired till the work was done. Of late years he found the labour of examinations, together with

WILLIAM ANDERSON, F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL; PROFESSOR OF ANATOMY TO THE ROYAL ACADEMY OF ARTS.

the ever increasing amount of operative work now expected of hospital surgeons, press somewhat hardly upon him But he suffered from no serious illness since an attack of enteric fever some years ago During the last week of his life he complained of severe dyspeptic troubles, such as he had suffered from before, but there was nothing to prepare his friends for the lamentably sudden termination of his life On the morning of Oct 27th he described himself to one of his colleagues as better, but still complained of indigestion In the afternoon he went for a drive and while in his carriage was seized with sudden and alarming syncope, and though able to reach home he rapidly sank The cause was found to be a rare and unlooked for accident, rupture of a cord of the mitral valve, without any other morbid condition of the heart or other organs

His funeral on Oct 31st was attended by the Treasurer and many members of the staff of St Thomas's Hospital, representatives of the Royal College of Surgeons of England, of the Japan Society, and by numerous private friends Thus passed away a man of singularly sweet nature, of perfect integrity, and of great attainments, whose loss will be felt, not only in his own hospital, but in the surgical profession of London and elsewhere Anderson was twice married—first to Miss Margaret Hall, who accompanied him to Japan, and by whom he has left a son and a daughter, and, secondly, to Louisa, daughter of the late Mr F W Tetley, of Leeds, who survives him

Our portrait is a reproduction of a photograph by Mr C T Dent

Mr R Clement Lucas sends us the following tribute to Mr. Anderson's memory —

"I cannot refrain from writing a few lines in appreciation of one whom I held in the highest esteem There are men whom we respect but who do not touch our hearts, men whom we admire who scarcely command even our respect, and men whom the world calls great who fail to raise in us the slightest sense of admiration Yet another, on whom, perhaps, the world smiles less kindly, catches at once our sympathy, and in a moment we feel instinctively that we are in the presence of a friend Such was the feeling inspired in me when I first met William Anderson And on what did this personal fascination depend? The rough pioneers who hack and hew their way into notoriety are not of this mould, nor are the laborious compilers of many volumes of ill assorted word heaps, nor the still more to be pitied collectors of endless figures they call statistics—all useful men, but all uninteresting It was Anderson's great good fortune to be always interesting To the mass of humanity a dead wood pigeon represents so many feathers towards a pillow and so much flesh for dinner, but to Anderson, whose gentle spirit had been fired by the light of genius, those iridescent plumes reflected beauty, those coral feet drawn to the grey bosom taught harmony in colour, and the half opened bill and dimmed and up-turned eye revealed the struggle of the fleeting spirit He was in sympathy with the beauties of Nature and his eye saw not form merely but the contour of a thought, and his ear heard not sound merely but the cadence of music Where Art reflected Nature truly there Anderson's mind found rest and pleasure Schooled to science his thoughts gravitated always in the direction of art, so that all felt when he was elected Professor of Anatomy to the Royal Academy of Arts that no better selection could have been made. His long sojourn in Japan made a lasting impression on him and his collection of Japanese art treasures became renowned and was purchased for the nation. His love of art and beauty we find reflected in his writings, and anything abnormal, unsymmetrical, or ugly caused in him a feeling of distress and a desire to remedy it So we find him editing Brücke's 'Beauties and Defects of the Human Figure' and publishing a small work on 'Deformities of the Fingers and Toes' I remember once when a very handsome but ignorant student appeared before him at an examination he drew the attention of his colleagues to this Apollo, and, as he did his duty, with a sigh said, 'Some woman has spoilt him' On another occasion when discussing a gentleman little favoured by nature he said, 'His ugly face has soured his life and spoilt his manners, I should like to try the effect of a wig and a beard' Thus to Anderson's æsthetic eye all ugliness excited pity and his imagination rose to suggest a remedy Though neither of commanding height nor of stalwart figure Anderson had a very distinguished appearance Only within the last three weeks I was strolling down Wimpole street with a friend when we met Anderson walking on the other side of the road 'Who is that very handsome man?' inquired my friend 'He has a very distinguished and somewhat foreign look' This was how Anderson struck a perfect stranger His somewhat prematurely whitened hair, worn rather long, and his full white moustache, contrasted with his darker eyes and brows Sensitive and retiring in disposition he nevertheless had a most courteous manner and a winning smile Not only by his own hospital and by her southern sister will his loss be mourned, but by many friends widely scattered who have known and appreciated his worth Our profession, so rich in men of surpassing industry, so full of men of mechanical genius, abounding, too, happily, in men of great self denial and benevolence, but bare—how sadly bare—of men who can with professional distinction carry with them an atmosphere of literary refinement and a true appreciation of beauty in Nature and Art can ill spare a man of Anderson's wide sympathies and will long feel the shock which his sudden death has caused"

ALFRED WILLIAM HUGHES, M B, C M, F R C S EDIN, F R C S ENG,

PROFESSOR OF ANATOMY, KING'S COLLEGE, LONDON

THE war in South Africa has occasioned many deaths in the medical profession, and the Welsh Hospital in particular has to mourn the loss of no less than five out of the staff of 23 a proportion greater than that ordinarily experienced in the fighting line. The death of Professor Hughes is peculiarly sad, since he had carried through with complete success the work which he had undertaken, and was already on his way home before the first symptoms of typhoid fever developed Some of those associated with him had thought that he was not in his usual health for two or three days before leaving Pretoria, while to others his unflagging cheerfulness masked the insidious onset of the disease Shortly after starting his temperature was found to be raised, but the chart kept during a bad passage showed no abnormal severity of fever On reaching home, however, his restlessness, delirium, and feeble pulse caused much anxiety, which was later increased by thrombosis of the femoral vein Although the obstruction to the circulation was comparatively slight the rapid feeble action of the heart persisted and signs of engorgement of the lung developed The end came a fortnight after landing at Southampton, and apparently on the twenty seventh or twenty eighth day of the fever During his illness after his return he was attended continuously by Dr Nestor Tirard and by Dr Frederick T Roberts

Professor Hughes was born at Fronwen, Merionethshire, and was the son of Mr Robert Hughes of that place He was educated mainly in Edinburgh, but he also studied in London and in Leipsic While he was an undergraduate at Edinburgh he gained a medal in anatomy and was junior demonstrator in anatomy and in physiology After graduation in 1885 he became in 1889 a Fellow of the Royal College of Surgeons of Edinburgh, and two years later he became a Fellow of the Royal College of Surgeons of England For a short time after graduation he was engaged in private practice at Flint but he gladly availed himself of an opportunity of returning to Edinburgh to resume work as an anatomist, at first as a senior demonstrator and afterwards as a lecturer At this time his writings and researches were numerous and important and he established a reputation as a teacher which led to his election to the chair of anatomy at University College, Cardiff Here his teaching was facilitated by his large private collection of anatomical preparations and the number of entries of students soon increased Owing to the continued illness of his wife he was compelled to remove from Cardiff after four years of successful work and he was then elected professor of anatomy at King's College, London Here he speedily won friends and became dean of the medical school in which capacity he represented the interests of King's College upon numerous committees He was peculiarly adapted to public life, and at one time he was a candidate for Parliamentary honours He had the instinct of the true sportsman which led him safely through difficulties, gaining friends even amongst those whose opinions might be at variance with his own, and part of the secret of his success appeared to lie in the invariable geniality and courtesy which never allowed him to say an unkind word of anyone It is needless to say that with students he was deservedly popular, not only were his teaching powers appreciated by them, but they also recognised in him one who could be counted upon to give them his sympathy and assistance in all their interests, and he accordingly figured frequently as chairman at concerts, sports, and dinners. Some of his colleagues and many of the students having gone in a surgical capacity to South Africa, Professor Hughes threw himself heart and soul into raising a fund for a Welsh military hospital. He was successful in collecting over £12,000, and the hospital was duly equipped and sent out in the middle of April. Within a few weeks, however, several of the staff died and Professor Hughes immediately volunteered to go out to assist in the work. In South Africa, as in England, his magnetic influence soon made itself felt, and the Welsh Hospital was so much appreciated that it was taken to Pretoria at the request of Lord Roberts. Professor Hughes has, since his return, received a further compliment to his successful organisation, Lord Roberts having sent a request that the Welsh Hospital might continue in work for another three months.

From the foregoing sketch of the more recent events in a life of stirring activity it must not be inferred that the progress of science was neglected. Professor Hughes has made numerous and valuable contributions to the advancement of the science of anatomy, and before he became engrossed in the interests of the Welsh Hospital he had been busily engaged upon a new book on anatomy which was nearly completed. In one sense his work is done, but he has left behind him an example of energy, of devotion to work and of interest in the well-being of students and of all who came within his sphere of influence, which will long continue to serve as a stimulus to all who have been privileged to know him.

We have received the following appreciatory remarks from the Chairman of the Welsh Hospital:—

Few persons are aware of the debt which the Welsh Hospital owes to Professor Hughes. Although several civil hospitals had been equipped and sent out to South Africa there was still need of more hospital accommodation; and in March Professor Hughes decided to send out a Welsh hospital. He gathered around him a few friends who supported him and, what was of far greater value, a number of ladies who worked admirably and successfully in furthering his efforts to collect funds and obtain hospital furniture and equipment, but the mass of the work fell on Professor Hughes. It was at a time when the country had liberally responded to large demands upon its benevolence in the cause of the war and when the prospect of success in obtaining the necessary funds was not of a cheering kind, but Professor Hughes's untiring energy, hopeful disposition, buoyancy of spirits, and enthusiasm drove away any doubts or misgivings about the ultimate result. In April the hospital was successfully equipped and sent out. On landing the staff was ordered to Bloemfontein to help to cope with the outbreak of typhoid fever which had broken out there after the battle of Paardeberg. They obeyed but suffered severely, for several of them died within five weeks of their arrival in South Africa. At this crisis Professor Hughes, who, as secretary and organiser, had worked with untiring zeal in the cause of the hospital, offered to go out to South Africa to undertake its management and to relieve the staff of all care and anxiety respecting the non-medical affairs of the institution. The committee accepted his generous and noble offer and within 48 hours he was steaming for Cape Town on his way to Springfontein where he remained until the hospital was removed to Pretoria. Under his management the hospital became such as to command general admiration from Springfontein to Pretoria. In September he received an intimation that the hospital would not be required as a medical and surgical hospital after the end of the month, but that Lord Roberts wished it to remain until Nov. 17th as a convalescent hospital. He made complete arrangements to carry it on in accordance with the Field Marshal's wishes and left Cape Town on Oct. 3rd, reaching home on the 19th to die for the Welsh Hospital.

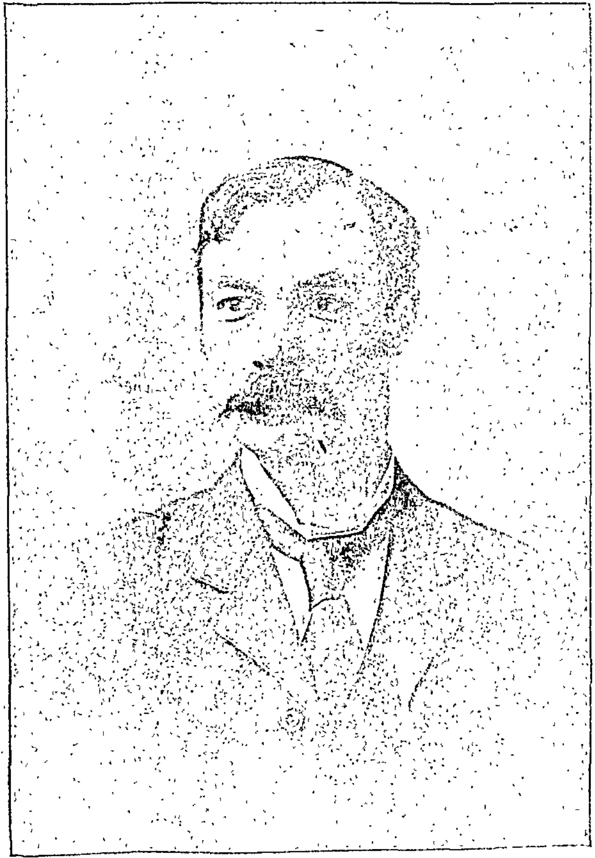
DAVID YOUNG, M.D., M.S. ABERD., L.R.C.P., L.R.C.S. EDIN.

THE death of Dr. David Young, at the age of 61 years, which occurred on Oct. 18th at Ventnor, in the Isle of Wight, has already been announced in our columns. Dr. Young received his professional education in Edinburgh and at the University of Aberdeen, where he graduated as B.A. and as M.S. in 1865, taking the degree of Doctor of Medicine in 1869. He became a Licentiate of the Royal College of Physicians and of the Royal College of Surgeons of Edinburgh in 1865. He made a special study of botany at the beginning of his medical career and in 1867 was appointed professor of botany in the Grant Medical College, Bombay. He also held a teaching appointment in the University of Bombay in obstetric medicine, but finding the climate of India very trying to his health he resigned these appointments and went to live at Florence, whence 10 years later—i.e., in 1882—he removed to Rome, where he continued to reside until quite recently when he retired to the Isle of Wight. When Dr. Young took up his residence in Italy there was scarcely a place in that country known to foreigners as a suitable health-resort during the summer months. Dr. Young visited the higher Apennines and other parts of Italy with a view to discover some place where invalids might pass the summer and he embodied the results of these observations in a book entitled "Rome in Winter and the Tuscan Hills in Summer." By this work, the gist of which appeared as a series of articles in the *Practitioner*, he did much to popularise Italy as a health-resort for English and American invalids.

Dr. Young was exceedingly popular among his patients and the following tribute to his merits from one of them shows why this was the case. "Dr. Young of Rome," writes an old friend, a layman, "was thorough. His patients came from everywhere, but whether they came once or for 'repairs' your individual case was for the moment the 'hobby,' and with soft sympathetic voice, gentle but firm persistency, he would dig through symptoms to the root of the matter. Many things combined to make Dr. Young an ideal continental practitioner. He had a charming personality, a fund of dry humour, a gift for languages, and was a wide reader and a travelled man who had seen and observed. But undoubtedly the chief factor in his success was his unusual powers of concentration upon the case before him. Adaptation of particular means to a particular end found a ready exponent in the old Piazza d'Spagna and the Via Venti Settembre. Dr. Young was wont to say that one of the greatest advantages and privileges of his early life had been to come under the favourable notice of Sir James Simpson. To him he owed not only example and precept, but his first professional appointment as surgeon to one of the preliminary search parties after the remains of Sir John Franklin and subsequently his connexion with the Grant Medical College, Bombay, which furnished experience peculiarly valuable to an Anglo-Italian medico. Invalided by a severe attack of dysentery in 1871, Dr. Young, almost by accident, settled in Florence until in 1882 he removed to Rome. Owing to the shortness of the season practice when it comes at all in the capital of Italy comes all at once, and for some few years the Embassy, under Sir Clare Ford, had been added to already too heavy and responsible work. In 1897, unmistakeable warning in the form of heart trouble suggested retirement. He fixed upon Ventnor as a haven of rest and passed the short time that remained happy among his flowers, full of interest to the last in works of charity and benevolence. By a coincidence, hard by his grave is the tomb of the late Professor Wharton Jones, who re-wrote the last edition of Sir James Clark's work on the climate of Rome—the only treatise on the subject until 1886 when Dr. Young published his 'Rome in Winter and the Tuscan Hills in Summer.' Any notice of Dr. Young would be inadequate if no allusion were made to his strong and deep religious convictions, his labours on behalf of the now demolished 'Ghetto,' or his self-forgetfulness and professional modesty. Reputation, honour, and esteem, indeed came, but they came from what he was and wrought, and came unsought."

JOHN TILSLEY, L.R.C.P. LOND., M.R.C.S. ENG.

MR JOHN TILSLEY died at the residence of his father, George-street, Bath, on Oct. 28th, from dysentery, in his thirty-second year. The deceased received his medical education at University College, Bristol, and took several prizes and scholarships. He qualified L.R.C.P. Lond. and M.R.C.S. Eng. in 1894, and after holding resident appointments at the Bristol General Hospital proceeded as a medical missionary to Kiu-Kiang, China. On the outbreak of the recent disturbances there he was



ALFRED WILLIAM HUGHES, F.R.C.S. ENG.,
PROFESSOR OF ANATOMY, KING'S COLLEGE, LONDON.

the Transvaal who have employed the apparatus indicate that, either for reasons of portability or owing to defects they were unable to use them in some instances where they might have been advantageously employed, there is little doubt that the majority of all such difficulties will by patient labour and preparation be avoided in the future

Speaking generally, we may say that critics of the military and medical operations in South Africa have not, we think, sufficiently kept in mind that the troops were fighting some 7000 miles from home and over an area of 160,000 square miles of territory.

In the War Office return issued on Nov. 2nd, showing the total reduction of the field force in South Africa, we find that up to, and including, October, there were 391 officers and 3795 men killed in action or died from their wounds, and that 155 officers and 6115 men died from disease out of a total of 10,698 deaths. Some 1422 officers and 33,077 men have been sent home as invalids, and among the latter only 1030 have left the service as unfit. These figures do not include those missing and prisoners or those who died in captivity or as invalids since leaving South Africa

---

We have received the following appeal from Lord Roberts, to which we refer in another column.

To the Editors of The Lancet.

Sirs,—Will you kindly allow me, through the medium of your paper, to make an appeal to my countrymen and women upon a subject I have very much at heart and which has been occupying my thoughts for some time past.

All classes in the United Kingdom have shown such a keen interest in the army serving in South Africa, and have been so munificent in their efforts to supply every need of that army, that I feel sure they must be eagerly looking forward to its return, and to giving our brave soldiers and sailors the hearty welcome they so well deserve when they get back to their native land.

It is about the character of this welcome and the effect it may have on the reputations of the troops whom I have been so proud to command that I am anxious and that I venture to express an opinion. My sincere hope is that the welcome may not take the form of "treating" the men to stimulants in public-houses or in the streets, and thus lead them into excesses which must tend to degrade those whom the nation delights to honour and to lower the "soldier of the Queen" in the eyes of the world—that world which has watched with undisguised admiration the grand work they have performed for their sovereign and their country.

From the very kindness of their hearts, their innate politeness, and their gratitude for the welcome accorded them, it will be difficult for the men to refuse what is offered to them by their too generous friends. I therefore beg earnestly that the British public will refrain from tempting my gallant comrades, but will rather aid them to uphold the splendid reputation they have won for the Imperial army.

I am very proud that I am able to record with the most absolute truth that the conduct of this army from first to last has been exemplary Not one single case of serious crime has been brought to my notice—indeed, nothing that deserves the name of *crime*. There has been no necessity for appeals or orders to the men to behave properly. I have trusted implicity to their own soldierly feeling and good sense, and I have not trusted in vain. They bore themselves like heroes on the battlefield and like gentlemen on all other occasions.

Most malicious falsehoods were spread abroad by the authorities in the Orange Free State and the Transvaal as to the brutality of Great Britain's soldiers, and as to the manner in which the women and children might expect to be treated We found on first entering towns and villages doors closed and shops shut up, while only English-born people were to be seen in the streets. But very shortly all this was changed. Doors were left open, shutters were taken down, and people of all nationalities moved freely about, in the full assurance that they had nothing to fear from "the man in khaki," no matter how battered and war-stained his appearance. This testimony will, I feel sure, be very gratifying to the people of Great Britain, and of that Greater Britain whose sons have shared to the fullest extent in the suffering as well as the glory of the war, and who have helped so materially to bring it to a successful close.

I know how keen my fellow-subjects will be to show their appreciation of the upright and honourable bearing as well as the gallantry of our sailors and soldiers, and I would entreat them, in return for all these grand men have done for them, to abstain from any action that might bring the smallest discredit upon those who have so worthily upheld the credit of their country.

I am induced to make this appeal from having read, with great regret, that when our troops were leaving England and passing through the streets of London their injudicious friends pressed liquor upon them and shoved bottles of spirits into their hands and pockets—a mode of "speeding the parting" friend which resulted in some very distressing and discreditable scenes. I fervently hope there may be no such scenes to mar the brightness of the welcome home.

I remain, Sirs, yours faithfully,

Roberts, F.M.

Headquarters of the Army in South Africa, Pretoria, Sept. 30th, 1900

THE SIEGE OF MAFEKING FROM A MEDICAL POINT OF VIEW.

By W. A. Hayes, M.R.C.S. Eng., L R C.P. Lond.,

PRINCIPAL MEDICAL OFFICER (BASE) DURING THE SIEGE; RAILWAY MEDICAL OFFICER (C G R.), SURGEON-LIEUTENANT, BECHUANALAND RIFLES.

It was my intention some time ago to have given the readers of The Lancet a slight sketch of the siege of Mafeking, but as I left that town immediately after the siege was raised with the column that went to the Transvaal and only returned a short time ago I could not manage it. The following may be of interest, however, to your readers, not so much from a scientific point of view as from a working one.

In August, 1899, I was in England on business, and knowing that war was a certainty I hurried back to Mafeking, arriving late in September. On my return I endeavoured, through the railway medical board in Buluwayo, to obtain as much in the way of surgical dressings as I could. Unfortunately, the order given was never executed, the time available being too short before the Boers declared war and cut us off both north and south. Major L. E. Anderson, of the Protectorate Regiment, was at that time stationed at Ramathlabama, in the Bechuanaland Protectorate, the Cape Government, for some reason best known to themselves, having refused to allow the force to remain here in Colonial territory. He also endeavoured to obtain supplies of various sorts from Cape Town, but failed. In his case, however, I believe there was no excuse, for the military authorities had large supplies there. As soon as Mafeking was invested by the enemy (at that time numbering about 6500) it was wonderful the way in which dressings, antiseptics, &c., appeared. A few packets of wool here, a bundle of bandages there—in fact, all we wanted turned up in all sorts of funny ways, and in a short time we had a decent collection.

Early in October, by order of the town commandant, I organised a number of dressing stations and appointed ladies to take charge of them. There were four of these stations with a Red Cross flag over each. Cronje, however, sent in word that he objected to the number of these flags flying in the town, so by the order of "the colonel" (Baden-Powell) I removed all but two. The enemy were informed where these two stations were, and where the hospital was, and also that the Convent was going to be used as a convalescent home. As, however, Cronje, and afterwards Snyman, were intent, not on shelling the forts but on merely sitting down round the place and trying to smash up the buildings in the town, including the hospital, the women's laager, and the Convent, and pumping shells and bullets promiscuously into the town, we did away with all Red Cross flags except those at the hospital and the Convent. At both of these places they were of no use as a protection against shell- and rifle-fire, but rather drew it, especially when Snyman was in command. During his *régime* the Convent was daily shelled so that we could only use the two south rooms for patients. No nurse or anyone else dared to appear outside the hospital or Convent without a volley being fired at them. Several patients were wounded on the hospital stoep. Those whose duty brought them to the Kaffir ward ran the greatest dangers. On one occasion Major Anderson and I were examining a patient there close to the open door when a volley was fired at us from about 1500 yards. Several of the bullets entered the ward, one passing between us and burying itself in the wall The sniping at the hospital got so bad at last that sandbags had to be put up all round the place I take this opportunity of stating that on no single occasion when an ambulance wagon, accompanied by a Red Cross flag, moved about inside our lines did it escape both wilful shelling and rifle fire, and on many occasions the Boers used their 15 lb high velocity gun and their "pom pom" for this purpose

At the commencement of hostilities the number of medical men in Mafeking was six Unfortunately, Mr Holmden of the British South Africa Police was ill and continued so for the greater part of the siege, so that he could do but very little Mr Elmes joined the ranks of the Bechuanaland Rifles The part played by Mr Sidney Smyth is explained by the orders of the day dated Nov 5th, 1899 Without going into further detail, therefore, I may say that the available number of qualified men was three—namely, Major L E Anderson, Mr T W Hayes, and myself The trained nursing staff at the hospital consisted of Miss K G Hill (Adelaide Hospital, Dublin), the matron (Miss J Gamble), Mrs Parminter, Mrs McCallum, Miss Cramer, and Miss Sheasby (a probationer) The following ladies also gave their help when required—namely, the Sisters of Mercy under Mother Theresa, Mrs Stuart, Mrs Girdwood, Mrs Adams, Miss Wyatt, and Miss Friend At the convalescent home which varied in its situation from time to time—the site having to be constantly changed on account of the enemy's shelling—the work was done all through the siege by Mrs More, Mrs Gemmell, and Mrs Hayes At first the Railway Institute was used as the hospital, but the enemy completely destroyed it one afternoon with a 94 lb shell which burst on the billiard table Both this hospital and the Convent were particularly dangerous on account of the shell fire and also from the constant sniping that went on at the nurses going and coming to the place When the bush had been cut down to a large extent for firewood all round the town we had to stop the ladies going to the Convent as it was too dangerous One lady had five shots sent at her when going along on her bicycle The sergeants' mess at the camp of the British South Africa Police was used as a hospital for the women's laager and Miss Crawford was placed in charge On May 12th the enemy took possession of the fort and all the buildings They brought their wounded to the hospital Mrs Buchan was there with her sister (Miss Crawford) assisting her As several of the Boers were dying from wounds Mrs Buchan came up to my house in the railway camp, a distance of 900 yards, under a heavy cross fire to get me to go down with her to their assistance As we did not ask the enemy to come there and as I personally had very little sympathy for people who had all along broken every rule of civilised warfare and sent their heavy shells into both of our hospitals, I at first thought the best thing was to leave them alone However, as Mrs Buchan would not remain away from her sister I returned with her The fire was extremely warm on the way there I amputated an arm and a leg for a couple of the enemy who were *in extremis* and after some time returned, bringing with me one of our men, a man of the Cape Police who had been sent to the fort before it was known that the enemy were there and who was badly wounded The journey there and back was not a pleasant one Neither of the two ladies in the hospital had the least idea of the dangerous position which they were in—not from the Boers so much as from the cross fire to which the building was subjected the whole day and which could not be avoided All through the siege every lady in Mafeking engaged in nursing the sick worked under conditions such as I hope no woman will ever have to live or work under again Ill fed (but with the best we could give them) and hard worked, in constant danger from shell and bullet, their true British pluck came out No order given was disobeyed, month after month was passed in the terrible heat and when we were constantly being disappointed by rumours of relief being close at hand, but no murmur was ever heard Every day women unaccustomed to such work or to the sights incident on war braced themselves together and held bleeding and mangled limbs whilst myself or my colleagues operated I am afraid that the public have heard very little of those ladies who did the really hard and dangerous work in attending the sick and wounded during the siege Like all true nurses they are satisfied with the thanks of their grateful patients and prefer not to see themselves figuring as heroines in the daily prints,

To give details of all the interesting cases would take too much space, so I will only give brief notes of a few of the most striking

Perhaps the most interesting case was that of one of the men in the railway division who was washing one evening after returning from his duties in the trenches He suddenly, as he describes it, "got knocked silly by a tremendous blow on the head" A Mauser bullet had entered the left side of his skull and had made an exit through the right side in a line as near as possible in the centre of each inferior frontal convolution measuring from before backwards When he was brought to the hospital he assisted to remove his clothing and answered questions and spoke quite rationally both then and at various times during the night, though he slept rather uneasily On the next morning when I saw him he had no recollection of all that had happened to him from the time he had felt the blow of the bullet to the moment I spoke to him He had a severe headache which lasted for a week Diplopia, which was well marked at first but gradually diminished, lasted for 10 days, at the end of which time he was quite well and his wounds had healed

Another interesting case was that of a man of the Cape Police He was injured by a Mauser bullet which entered the body at the level of the junction of the sixth rib and the costal cartilage about two inches to the outer side After having passed through the liver it must have gone through the right kidney and then through the muscles and integuments of the back, making its wound of exit just above the posterior superior iliac spine He complained of very severe pain in the right knee and on the inner aspect of the thigh, which lasted for 34 hours, but hardly any abdominal pain was present There were no lung symptoms Hæmaturia was well marked for two days and then disappeared On the third day the patient was to all intents and purposes well We kept him in bed for a week, greatly against his will, as he was anxious to return to duty and 'wipe out the insult"

The following case of a native is also interesting A "pom pom" shell came through the wall of the hut in which he was sitting and exploded A piece of the shell struck him, but so slight was the pain caused by the blow that he was not quite sure "if it had gone in" There was a small wound in the flank, and from that a contused line led downwards, in the middle of which was a lump such as would be caused by a blow, A probe would not pass beyond this point on the first day Two days after on account of the appearance of pus at the lower wound I probed again, when suddenly the probe slipped along and struck metal, and I sent for Major Anderson to have a look at the patient with me We decided to cut down on the end of the probe and we did so I made an opening large enough to pass my little finger, and at once recognised the point of a "pom pom" shell Nearly half of the shell, must, after having passed the lower opening, grooved the brim of the pelvis, then turned downwards and inwards along the outer surface of the ilium and afterwards turned directly upwards and outwards Having enlarged the wound I made a hook on the end of the probe and, passing it into the powder chamber of the shell by steady pulling and enlarging the wound, got it out It was remarkable that the probe would not pass with ease the first time considering the size of the wound The fact that the point of the shell was pointing outwards was a thing we constantly noticed with bullets They were nearly always found where they were lying under the skin opposite the wound of entrance in a position pointing towards that wound During the removal of the fragment of shell the patient was not under an anæsthetic He apologised to me afterwards for making so much noise during the operation; as a matter of fact he had only given one or two grunts On May 10th or 11th the patient went out of hospital and arranged a looting tour through the Transvaal He and his party got ambushed, however, too close to a Maxim and suffered the penalty

Amputation we found to give the best results from a surgical point of view In spite of the want of proper dressings towards the end of the siege and the overcrowded state of the hospital, we never had a wound which became septic Two cases of gangrene occurred but they were the consequence of the tremendous injuries inflicted, not from failure of antiseptics The hospital, constructed for 47 patients always had from 50 to 70 and more often 100

Of wounds those from the Mauser and Mannlicher bullets, which are indistinguishable, did best We had many cases in which the bullets had passed through joints, which all did well, and after healing regained good movement under massage and calisthenics We had some few cases in which bones had been drilled perfectly cleanly, with no splintering or fracturing accompanying. The Lee-Metford bullet gives more trouble, but, speaking generally, inflicts an easily treated and clean wound. The Martini bullet gives an ugly wound and when it strikes bone does great damage. The enemy used the true explosive bullet as well. We had from time to time several cases which we suspected to be due to explosive bullets, and at last we got one where a bullet, exploding in the loophole, tatooed a man's face with powder and peppered him with lead. Major Anderson attended the man on admission to hospital. I afterwards saw him with Major Anderson and there was no shadow of doubt about it. Mauser, Lee-Metford, and Martini expanding bullets (soft-nosed) were used constantly. Shell-wounds were the most troublesome wounds, even when they were very slight. Of two cases of enterostomy we performed for shell-wounds one recovered. In each case the abdominal wall was badly damaged. Bullet-wounds of the abdomen we left alone and treated by opium and feeding. These patients all died. In spite of opinions expressed by high authorities I think we might have saved one or two by operating, as in the case of the shell-wounds mentioned above. No argument can convince me that a hole in the bowel, or two or three of them, would not give the patient a better chance by being closed. All our patients so wounded died from septic peritonitis or hæmorrhage.

STATEMENT OF ADMISSIONS, DISCHARGES, AND DEATHS AT THE VICTORIA HOSPITAL, MAFEKING, FROM OCT. 13TH, 1899, TO MAY 16TH, 1900, INCLUSIVE.

Medical cases, especially typhoid fever and dysentery, we had some trouble in treating owing to the scarcity of milk. Everyone, with a few exceptions, gave up all his fresh milk to the hospital, for which we were deeply grateful, but even so the supply was shorter than the demand. Commandeering only made matters worse. Malarial fever was bad and of a bad type. This was to be expected, as the men had to live all day in newly-dug trenches; besides we had extremely heavy and "out of-season" rains. In 1898 we had the same condition practically along the Bechuanaland Railway north of Mafeking, and never before or since has there been so much fever in the immediate vicinity of the railway, where at that time a great deal of virgin soil was disturbed followed by heavy "out-of-season" rains. The fever then also was of a bad type.

The food-supply, composed of various army rations, and an occasional ox, was nourishing enough, but the amount was limited. Towards the end of the siege horses, mules, and donkeys were eaten. A quart of "sowens" was daily given out as an addition to the half ration. "Ryan buns" (from Captain Ryan) were the salvation of the place. They were made from the Scotch oats imported for the horses. After being ground and the husks sieved off a six-ounce bun was made of the flour to which a very small portion of lard was added. Owing to no proper wire gauge being available the flour was a little coarse and husky, but it was nutritious, and, in spite of grumbling amongst unreasonable people it was eaten by all. There is no doubt we all knew what hunger was, and there was no one who was not constantly in a state of longing for a "good feed." Personally, about the last two months of the siege I got a terrible craving for white bread and would have purchased flour at any price could it have been obtained. I was not alone in this feeling, which I ascribe to a systemic starvation from the want of wheat-flour supplies. Of the three meats, horse, mule, and donkey, the latter is by far the best and most palatable. Horse and mule flesh is most indigestible and unsatisfying, especially when almost skin and bone. A brawn made of the skins of these animals with scrapings of the heads and bones highly flavoured with spices was absolute filth, but nevertheless was sold rapidly by the military authorities at 1*s.* per pound, and was eagerly eaten by the defenders as a means of "filling up the cracks" in a half-ration diet. Constant watching—and there were none who did not watch to a large extent—and short rations, however, were bound to tell on us sooner or later. We could defend our town, but I feel quite certain that to march three miles and fight could never have been done at any time after the middle of February. It was remarkable how little time it took to get the defending force fit to march when full rations were dealt out, which I ascribe to the removal of anxiety as much as anything else. We knew what our fall meant to the nation, and our anxiety was for that, not for ourselves. No one would ever have been taken alive here. The word "surrender" was never once heard during our long siege in Mafeking. When it is understood that with 1200 men at the end of the siege we defended a front of 13 miles against a much shorter front at the beginning of the siege with 1500 men it will be realised what mental and bodily strain there must have been. No post had a decent body of men to defend it and some had only four or five men. At one point we were 65 yards from the enemy, near enough to throw stones into their trench and to have them sent back to ours.

I append a table from which you will see the numbers of sick and wounded respectively that we dealt with during our seven months' enforced retirement and the mortality, which considering everything is extremely light. In all 767 of the working garrison passed through hospital out of roughly speaking 1500 men.

Mafeking, Rhodesia.

THE IMPERIAL YEOMANRY FIELD HOSPITAL AND BEARER COMPANY.

By CHARLES STONHAM, F.R.C.S. ENG.,

CHIEF SURGEON AND OFFICER COMMANDING THE IMPERIAL YEOMANRY FIELD HOSPITAL, SENIOR SURGEON, WESTMINSTER HOSPITAL, ETC.

I feel sure that you and our friends and colleagues at home will be interested to hear something of the doings of the Imperial Yeomanry Field Hospital and Bearer Company, occupying as they do a unique position as being the only field hospital and bearer company which has ever left the country under civil auspices. Let us hope that we shall but prove to be the pioneers of many such should the needs of the Empire unfortunately require their services.

Before leaving England I heard it asserted more than once that although civilians would prove of inestimable benefit in supplying the needs of stationary and base hospitals they could not succeed in the more arduous and hazardous duties of caring for the wounded on the field, nor would they themselves be fitted to withstand the fatigues and hardships necessarily entailed by marching with an army at the front. The career of our field hospital and bearer company has abundantly proved that doubts such as these are unfounded, and I venture to express the opinion that when the final verdict is passed upon our work even the most captious must fain admit that the Imperial Yeomanry Field Hospital and Bearer Company have fully justified the most sanguine hopes of those who so patriotically equipped and sent them out

I have the good luck to have associated with me Major G E Hale, D S O , R A M C , who is in command of the bearer company No man could be more agreeable as a companion and fellow worker, and his expert knowledge of transport and camp life has been of the utmost service, if all men of the Royal Army Medical Corps had the excellent personal and professional calibre of Major Hale, we should hear, instead of carping censure, unqualified admiration for the corps to which he belongs Non commissioned officers and men have, as a whole worked hard and well, comparing most favourably with men of the regular army, and as the majority of them are but 'prentice hands they are much to be commended

In this and in my succeeding letters I propose to give a brief outline of the work which we have done On leaving England our great anxiety was that the war would be over before we could reach Cape Town, now our aspirations are in an opposite channel and our thoughts are turned homewards Our mental condition has undergone much the same change as did the lady's on her first voyage—for the first 24 hours she expressed fears that the ship would go down and during the next few days she was afraid it would not By the way our voyage was not propitious, for, as is well known, our transport, the *Winkfield*, collided with and sank the Union liner *Mexican* 70 miles from Table Bay

Had we known the country to which we were going we should not have had any anxiety as to the speedy termination of the war The British are fighting physical geography rather than a people, and those who have been out here and have seen what we have seen will be the most lenient in their judgment of reverses and checks, which are so easily condemned by some who have only the morning paper as a source of information and know only the physical character of their own country

Since we left England we have marched from Bloemfontein on May 28th up to the present date 1150 miles, have been present at 11 engagements, and have afforded relief to 1850 patients; we have admitted 650 men into hospital who have been carried by the bearer company's ambulances, sometimes for days and for long distances, until they could be sent by sick convoy to the nearest stationary or base hospital

We arrived in Table Bay on April 6th, and as our ship was considerably damaged in the collision we were at once sent into the dock instead of waiting our turn to disembark I need not dwell upon the difficulties which we experienced in Cape Town in being sent on, at last they were overcome and we entrained on April 29th to proceed north, although our actual destination was apparently unknown However, in due course we arrived at Bloemfontein on May 2nd, having stopped a few hours at Deelfontein to see the Yeomanry Base Hospital and to have breakfast with our numerous friends there At fever stricken Bloemfontein we were allotted camping ground in the foulest place which I have ever seen, and here we waited till May 28th before we could get transport animals We here packed our wagons and made all ready for a start as soon as we should get orders On May 28th we marched under orders to proceed to Kroonstad We were quite alone and had no escort, indeed, we marched alone as far as Pretoria, a very different condition of things as we were to find later, to forming part of an advancing army We arrived at Kroonstad on June 4th, drew four days rations and started on the next morning for Johannesburg, but we were not destined to reach there so quickly as we thought It is now well known from my telegrams and letters that we were present at the action on June 7th when the Boers, under General C de Wet, destroyed the line at Rhenoster river, cut up the 4th Derby Militia, and destroyed our mails, stores, warm clothing, and ammunition at Roodevaal station which they eventually blew up It was here that we first came under fire, the Boers, mistaking us for a convoy and reinforcements, firing on our wagons but fortunately doing no harm They, however, made us prisoners, but gave us every facility for carrying on our work and showed us many kindnesses until they were driven back by Lord Methuen on June 11th after which action we admitted to our hospital 12 wounded Yeomen

On June 7th we had 29 killed and 91 wounded, the latter keeping us hard at work for two days, many of these men had been injured by fragments of shell, the wounds in some cases being exceedingly severe, the soft structures being lacerated and the bones much comminuted Our arrival on the scene was providential Dr Buchanan, the regimental medical officer attached to the Derbyshires was singlehanded, and had not the necessary equipment with him for dealing with so many severe cases, even if it had been in the power of one man to do so

Our experiences at Rhenoster river were most interesting and I think I may say unique, but as my letters already referred to have given a short account of them I need not dwell on them further It was most unfortunate that we had to move on June 9th, a step rendered imperative by the impending action (June 11th) as De Wet meant to occupy the kopje beneath which we were, and moving the patients necessarily entailed considerable suffering and, I regret to say, cost some lives which would, I think, have otherwise been saved On June 11th, after the action, Lord Methuen came round the hospital, saw all the wounded men, and expressed his satisfaction with our arrangements With the advent of such a large force we of course became very busy, as it soon became known that our equipment was all that could be desired

On June 14th we sent a sick convoy of 108 by road to Kroonstad, our ambulances taking them all under Major Hale's command He returned on June 18th, and on the following day I took a further convoy of 102 by train, returning on the next day

On June 22nd we struck camp and proceeded on our way to Johannesburg arriving there on the 27th and encamped in the grounds of the Wanderers' Club

On June 29th we set out for Pretoria and reached there on the next day, when I had an interview with Lord Roberts in reference to our experiences at Rhenoster river, as the result of which he wrote to General de Wet thanking him for his kindness to us during the time we were in his hands We remained at Pretoria until July 7th (camping at Arcadia), when we received orders to march and join General Mahon's brigade which was at Reitfontein, near Irene Failing to come up with him there we were to continue our march until we found him Accordingly we marched to Reitfontein, but the brigade had left, so the next day we determined to push on although we had no means of finding out where General Mahon was but an officer commanding a detachment of Irish Fusiliers who were holding a position near our camp told us he thought Mahon was at Baasfontein We eventually found the brigade, which had joined General Hutton, at Reitfontein No 6, but on our way we nearly marched into the Boer lines, for we had taken a wrong road and only discovered our mistake when we saw and questioned our own advanced outposts whose line we had passed through

On July 9th, 10th, and 11th we sent out ambulances as fighting was in progress, but we had very few casualties, the Boers being strictly on the defensive

On July 12th the camp broke up and the force marched back to Pretoria, we, however went with 50 sick to Springs where we arrived late in the afternoon and were lucky enough to be able to send the sick to Johannesburg on the same evening by train On the following day we telegraphed to the principal medical officer, Pretoria for instructions and received orders to return to Pretoria at once We marched on July 15th, arriving at our destination on the 17th Up to this time we had been marching by ourselves, but we were to become part of an advancing force particulars of which I shall give you in my next letter

Barberton Sept. 20th

NOTES FROM SOUTH AFRICA

(FROM OUR TRAVELLING CORRESPONDENT)

I arrived at Pretoria four days ago (Oct 1st) after an uneventful journey from Kroonstad Nearly two months have elapsed since my previous visit and during that time the aspect of the town has considerably changed The pretty little capital of the Transvaal has been so beautified by the advent of the South African spring that I should hardly have known it again The stately blue green trees and the enormous weeping willows which adorn the chief streets and avenues are now clothed in vivid green and the gardens of the numerous villas are filled with flowers The cloudy sky and the misty atmosphere—heralds of the approaching rainy season—have softened the sharp outlines of the surrounding hills, and the general effect produced is more that of an English than of an African landscape Though the nights are fairly cool the heat at noon-day is now somewhat oppressive, the climate is more "relaxing" than ever, and most newcomers complain of indefinable languor and indisposition to exertion.

The military medical arrangements are now, and have been for some time, complete and in full working order. The hospitals are fairly full, but chiefly with mild or convalescent cases, and they can be readily depleted at any moment by the hospital train service and the convalescent camps. The following is a complete list of the military hospitals now established at Pretoria and in its environs. For convenience of administration the town is divided into an eastern and a western section. In the eastern section are comprised No. 2 General Hospital, the Welsh Hospital (this has just been amalgamated with No. 2 General Hospital), Langman's Hospital, the Imperial Yeomanry Branch Hospital, No. 2 Infectious Hospital, the Nursing Sisters' Hospital, and a convalescent camp. In the western section there are No. 1, No. 2, and No. 3 Model School Hospitals, the Palace of Justice Hospital (which includes the *personnel* of the Irish Hospital), the Racecourse Hospital, the Railway Rest Hospital, No. 1 Infectious Hospital, and the Native Followers' Hospital. Of these the three large hospitals—No. 2 General Hospital, the Imperial Yeomanry Hospital, and the Palace of Justice Hospital—can take nearly 2000 patients. Including the smaller hospitals and the convalescent camp, Pretoria has now accommodation for upwards of 4000 sick men. The total number of patients in hospital four days ago was 1997. Of these 242 were suffering from enteric fever, 180 from "other fevers" (including malarial fever, simple continued fever, and a few cases of measles and diphtheria), and 149 from gunshot wounds. The comparatively small number of cases of enteric fever and "other fevers" is a cheering sign, but old residents prophesy a recrudescence of fever after the rains.

The Princess Christian Hospital train came into Pretoria on the day after my arrival, and through the courtesy of Dr. Percy Lowe, the medical officer in charge, I was enabled to take a short trip to Charlestown, in the north of Natal, and back in this beautiful train. Our route lay *viâ* Elandsfontein, Heidelberg, and Standerton, through a pretty country of rolling downs. This part of the Transvaal much resembles the Wiltshire downs in its general features. The line between Elandsfontein and Charlestown is closely guarded, as small bodies of the enemy are still lurking in the neighbourhood. At Standerton is No. 4 Stationary Hospital, a large marquee hospital of, I should think, some 400 beds, but time did not permit of a visit. Charlestown, where the train unloaded, is a tiny town just within the Natal border. No. 1 Stationary Hospital is established here, a beautifully laid out hospital of 500 beds. A stay of a few hours at Charlestown just allowed me time enough to visit Majuba Hill and Laing's Nek, names which recall sad memories to English ears.

On our return to Pretoria we found both No. 3 (under Major Russell) Hospital train and No. 5 Hospital train (under Major M. T. Yarr) in the station, and I had an opportunity of comparing these trains, which may be considered types of the five Government trains proper, with the Princess Christian train. The Princess Christian train, unlike the others, was specially designed and built as a hospital train. As it has been frequently described with great minuteness I merely give a general sketch of its arrangements here for the purpose of comparison. It is composed of seven "bogey" cars, each painted white outside and adorned with red crosses and "Princess Christian Train" in gold letters. The first car contains a foul linen store and two beds for nursing sisters in one room and two beds for sick officers in another. The second car has two beds for medical officers, a mess-room, a dispensary, and a pantry. The position of the foul linen store is, on the face of it, a most undesirable one and is a grave blot on the general design. I think, personally, too, that the presence of sick officers in the staff carriages is an objectionable feature. The third, fourth, fifth, and sixth cars are for patients. Each car carries 18 patients and four orderlies. Including two sick officers the whole train thus carries 74 patients (22 less than the Government trains). The wards are fitted with removeable iron cots in three tiers. The whole interior is beautifully decorated, the beds have pretty coverlets, and the general effect is wonderfully bright and cheery. Each ward has a fixed wash-basin, a pretty stove, and a water closet. The moveable cots are a very great advantage, as they enable patients to be transferred from stretchers into cots outside the train, but I think that three tiers are a tier too many. The seventh and last car is the kitchen car; it is beautifully fitted up, but is in a most inconvenient position at the extreme end of the train. There is no pack-store car—a very serious omission. An ordinary short railway truck has had to be added to receive men's kits, but there is no through communication between it and the rest of the train so that kits cannot be sorted *en route*. There should, of course, have been a special pack-store car, part of which could have been used as a foul linen store, as in the Government trains. The position of the foul linen store, the absence of a pack-store, and the three-tier arrangement of the cots are the main defects in the design of the Princess Christian train. Apart from these defects it is a beautiful hospital on wheels in which patients enjoy every luxury and comfort that money can buy. The staff is practically the same as that of the Government trains—two medical men (at the present moment there is only one), two nurses, one civil compounder, one *chef*, and 19 rank and file.

Speaking generally, the five Government hospital trains are of the same type, and they are all composed of converted passenger cars. Each train is made up of seven "bogey" cars—longer and wider than in the Princess Christian train—arranged in the following order. First the staff car, a first-class saloon car of five compartments, two of which are occupied by the medical staff and two by the nursing staff, the fifth being used as a staff mess room. The second is the kitchen car, with orderlies' bunks on one side of the kitchen and the dispensary on the other. The third, the fourth, the fifth, and the sixth are long corridor cars gutted and fitted with bunks, each car containing 24 beds in two tiers, with a water-closet and a lavatory at each end. The seventh is the pack-store, linen store, and stewards' store. Four beds in each ward are screened off by curtains and may be used for officers. Each train thus carries 96 patients, of whom 16 may be officers. The carriages might be better ventilated. The cots—except in No. 4 train—are fixed, and the trains, though scrupulously clean, are not so prettily got up, either internally or externally, as the Princess Christian train. On the whole, however, they are very practical and have worked exceedingly well throughout the campaign, and many people prefer their general arrangement to that of their beautiful rival. The so-called "Boer Ambulance" train is composed of two captured Boer ambulance carriages—large and well-ventilated, but without water-closets and roughly put together—to which an indefinite number of ordinary saloon cars are added; it is only used for convalescents.

Pretoria, Oct. 4th.

THE MEDICAL STAFF AND THE BOARD OF MANAGEMENT OF THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

THE following important communication has been addressed to the editor of the *Times*:—

SIR,—The controversy which has been carried on in your columns between the board of management of the National Hospital for the Paralysed and Epileptic and its medical and surgical staff is of public importance. The main point for which the staff of the hospital is struggling is a moderate representation on the board of management, the absence of which has led to irritating friction and to the present unhappy state of affairs.

It is impossible that the inclusion of representatives of the staff could do otherwise than strengthen the board of management in wisely carrying on the great charitable work with which it is entrusted by the governors.

From long experience of hospital administration we desire to record our firm conviction that the demand of the staff for representation on the board of the hospital is a perfectly reasonable one and one which in other hospitals has conduced to harmonious working and efficient administration.

We venture to express the hope that the board of management and the governors will put an end to this controversy by granting the representation asked for, in order that the hospital, whose reputation is more than national, may continue its career of usefulness,

We are, Sirs, yours, &c.,

Lister; William H. Broadbent, M.D., F.R.C.P., F.R.S.; John Williams, M.D., F.R.C.P.; J. Fayrer, K.C.S.I., F.R.S.; Henry Thompson, F.R.C.S.; William MacCormac, K.C.V.O., F.R.C.S.; J. Burdon Sanderson, F.R.S.; R. Douglas Powell, M.D., F.R.C.P.; Samuel Wilks, M.D., F.R.C.P., F.R.S.; Walter Foster, M.P., M.D.; John Batty Tuke, M.P., M.D.; W. B. Dalby, F.R.C.S., St. George's Hospital; Dyce Duckworth, M.D., F.R.C.P., St Bartholomew's Hospital; T. Hood, M.D., F.R.C.P., West London Hospital; Henry G. Howse, M.S., F.R.C.S., Guy's Hospital; C. B Keetley, F.R.C.S., West London Hospital; D. B. Lees, M.D., F.R.C.P., St Mary's and Great Ormond-street Children's Hospitals; Stephen Mackenzie, M.D., F.R.C.P., London and Royal Ophthalmic Hospitals; J. Macready, F.R.C.S., Great Northern Hospital; Howard Marsh, F.R.C.S., St. Bartholomew's and Great Ormond-street Children's Hospitals; Henry Morris, M.A., F.R.C.S., Middlesex Hospital; William M. Ord, M.D., F.R.C.P., St. Thomas's Hospital; Edmund Owen, F.R.C.S., St Mary's Hospital; F. W. Pavy, M.D., F.R.C.P., F.R.S., Guy's Hospital; Bernard Pitts, M.A., F.R.C.S., St Thomas's and Great Ormond-street Children's Hospitals; James E Pollock, M.D., F.R.C.P., Brompton Hospital; Sydney Ringer, M.D., F.R.C.P., F.R.S., University College Hospital; Frederick T. Roberts, M.D., F.R.C.P., University College Hospital; William Rose, F.R.C.S., King's College Hospital; Seymour J. Sharkey, M.D., F.R.C.P., St. Thomas's Hospital; Walter G. Spencer, M.S., F.R.C.S., Westminster Hospital; Waren Tay, F.R.C.S., London and Royal Ophthalmic Hospitals; Frederick Taylor, M.D., F.R.C.P., Guy's Hospital; Frederick Treves, F.R.C.S., London Hospital; Samuel West, M.D., F.R.C.P., St. Bartholomew's and Royal Free Hospitals; Alfred Willett, F.R.C.S., St Bartholomew's Hospital; C. Theodore Williams, M.D., F.R.C.P., Brompton Hospital; I. Burney Yeo, M.D., F.R.C.P., King's College Hospital.

THE PLAGUE.

PLAGUE IN GLASGOW.

SIX weeks have now elapsed since any fresh case of plague was notified in Glasgow. The last plague patients in the Belvidere Hospital were discharged on Nov. 3rd, so that if no fresh case should arise in the interval Glasgow will be able to be officially declared free from plague at the expiration of 10 days from that date—namely, on Nov. 13th.

PLAGUE IN BREMEN.

A fatal case of plague is reported from Bremen. It occurred in the person of a seaman on board a steamer trading from Buenos Ayres. The steamer arrived at Bremen on Oct. 27th and from that date to Oct. 30th the patient was in a private house from which he was removed to the hospital, where he died on Nov. 5th. All necessary precautions as to disinfection and isolation of "contacts" are being taken.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6379 births and 3908 deaths were registered during the week ending Nov. 3rd. The annual rate of mortality in these towns, which had been 17·1, 17·1, and 17·3 per 1000 in the three preceding weeks, further rose last week to 17·5. In London the death-rate was 16·7 per 1000, while it averaged 18·1 in the 32 provincial towns. The lowest rates in these towns were 9·1 in Norwich, 10·3 in Croydon, 13·4 in Cardiff, and 13·6 in Leicester; the highest rates were 21·2 in Sheffield, 22·4 in Gateshead and in Manchester, 23·4 in Liverpool, and 25·5 in Salford. The 3908 deaths in these towns included 425 which were referred to the principal zymotic diseases, against 468 and 485 in the two preceding weeks; of these, 121 resulted from diarrhœa, 94 from diphtheria, 81 from "fever" (principally enteric), 49 from measles, 44 from whooping-cough, and 36 from scarlet fever. The lowest death-rates last week from these diseases occurred in Plymouth, Bristol, Cardiff, and Bradford; and the highest rates in West Ham, Leicester, Birkenhead, Burnley, Blackburn, and Sheffield. The greatest mortality from measles occurred in Brighton and Swansea; from whooping-cough in Gateshead; from "fever" in Portsmouth, Birmingham, Birkenhead, and Blackburn; and from diarrhœa in Manchester, Burnley, Huddersfield, and Halifax. The mortality from scarlet fever showed no marked excess in any of the 33 towns. The 94 deaths from diphtheria included 42 in London, seven in West Ham, seven in Leicester, four in Portsmouth, four in Liverpool, and four in Sheffield. No fatal case of small-pox was registered last week either in London or in any of the 32 large provincial towns; and only one small-pox patient remained under treatment in the Metropolitan Asylums hospitals on Saturday last, Nov. 3rd. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2619, against numbers increasing from 1703 to 2489 on the nine preceding Saturdays; 336 new cases were admitted during the week, against 322, 328, and 320 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 164 to 236 in the four preceding weeks, further rose last week to 267, but were 108 below the corrected average. The causes of 57, or 1·5 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Bradford, Leeds, Newcastle, and nine other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·5 and 19·6 per 1000 in the two preceding weeks, was again 19·6 during the week ending Nov. 3rd, and was 2·1 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 11·3 in Leith and 15·1 in Edinburgh, to 22·4 in Glasgow and 24·6 in Paisley. The 607 deaths in these towns included 24 which were referred to diarrhœa, 18 to whooping cough, 12 to "fever," eight to measles, eight to scarlet fever, and seven to diphtheria. In all, 77 deaths resulted from these principal zymotic diseases, against 67 in each of the two preceding weeks. These 77 deaths were equal to an annual rate of 2·5 per 1000, which was 0·6 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had decreased from 53 to 25 in the four preceding weeks, further declined last week to 24, of which 14 occurred in Glasgow, four in Dundee, and three in Edinburgh. The deaths from whooping-cough, which had increased from 13 to 18 in the three preceding weeks, were again 18 last week, and included 15 in Glasgow. The deaths referred to different forms of "fever," which had been six and four in the two preceding weeks, rose again last week to 12, of which eight were registered in Glasgow and two in Greenock. The fatal cases of measles, which had been two and four in the two preceding weeks, further rose to eight last week, and included five in Aberdeen and two in Edinburgh. The deaths from scarlet fever, which had been five and eight in the two preceding weeks, were again eight last week, and included five in Glasgow and two in Paisley. The fatal cases of diphtheria, which had been eight and six in the two preceding weeks, rose again last week to seven, of which three were recorded in Edinburgh and two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 98 to 139 in the four preceding weeks, further rose last week to 148, and showed an excess of 31 over the number in the corresponding period of last year. The causes of 34, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·4, 24 9, and 20 0 per 1000 in the three preceding weeks, rose again to 21·9 during the week ending Nov. 3rd. During the past four weeks the death-rate in the city has averaged 23 3 per 1000, the rate during the same period being 15 8 in London and 15 2 in Edinburgh. The 147 deaths belonging to Dublin registered during the week under notice were 13 in excess of the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against numbers declining from 36 to 12 in the four preceding weeks; of these, five resulted from diarrhœa, three from whooping-cough, three from "fever," one from measles, and one from scarlet fever. These 13 deaths were equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 1·4 both in London and in Edinburgh. The fatal cases of diarrhœa, which had decreased from 27 to six in the four preceding weeks, further declined last week to five. The deaths from whooping-cough, which had been two in each of the two preceding weeks, rose to three last week. The fatal cases of "fever," which had been five and four in the two preceding weeks, further declined to three last week. The 147 deaths in Dublin last week included 26 of infants under one year of age and 35 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons considerably exceeded the number in the preceding week. Six inquest cases and six deaths from violence were registered, and 69, or nearly one-third, of the deaths occurred in public institutions. The causes of seven, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

Fleet Surgeon (retired) Alfred Gideon Delmege, M.V.O., has been allowed to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointments are notified:—Fleet Surgeon E. W. Luther to the *Hood*. Staff Surgeons; J. H. Whelan to the *Hood* and J. McElwee to the *Pioneer*. Surgeons: A. H. H. Vizard to the *Boscawen* for the *Agincourt*; H. I. Rogers to the *Northampton*; E. O. Cridland to R.M. Depôt, Deal; M. H. Knapp to the *Wildfire*; H. R. Gardner to the *Hood*; A. J. Laurie to the *Cambridge*; O. S. Facey to the *Vivid*; W. K. Hopkins to the *Wye*; and J K. Raymond to the *Wildfire*.

Royal Army Medical Corps.

The under-mentioned officers of the Royal Army Medical Corps are granted the local rank of Surgeon-General whilst Principal Medical Officers, Lines of Communication, South Africa:—Colonel W H. McNamara, C.B., and Colonel J. A. Clery. Colonel J. F Supple is granted the local rank of Surgeon-General whilst Principal Medical Officer at the Base, Cape Town. Colonel T. Gallwey, C.B., is granted the local rank of Surgeon-General whilst Principal Medical Officer, Natal. The undermentioned officers are granted the local rank of Colonel whilst Principal Medical Officers of Divisions, Field Force, South Africa:—Lieutenant-Colonel S. H. Carter, Lieutenant-Colonel C. Todd, Lieutenant-Colonel G. T. Goggin, Surgeon-Lieutenant-Colonel J. Magill, Coldstream Guards, and Major B. M. Skinner The undermentioned officers are granted the local rank of Colonel in charge of General Hospitals, Field Force, South Africa:—Lieutenant-Colonel Morgan D. O'Connell, Lieutenant-Colonel A. Keogh, Lieutenant-Colonel H. Martin, Major T. R. Lucas, Major H. J. Barratt, and Major S. Westcott. The undermentioned officers are granted the local rank of Colonel whilst Principal Medical Officers of Divisions in South Africa:—Lieutenant-Colonel J. D. Edge Lieutenant Colonel W. Donovan, Lieutenant Colonel R W. Mapleton, Lieutenant-Colonel, J. A. Gormley, and Lieutenant-Colonel W. A. May. The undermentioned officer is granted the local rank of Colonel whilst Principal Medical Officer of a Division and Principal Medical Officer of the Field Army, Natal:—Lieutenant-Colonel W. B. Allin. The undermentioned officer is granted the local rank of Colonel whilst Principal Medical Officer of a Division and Principal Medical Officer at Pretoria:—Lieutenant-Colonel W. L. Gubbins. The undermentioned officers are granted the local rank of Colonel whilst in charge of General Hospitals in South Africa:—Lieutenant-Colonel O. G. Wood, Lieutenant-Colonel J. O Dorman, Lieutenant-Colonel J. F. Williamson, Lieutenant-Colonel B. W. Somerville-Large, Lieutenant-Colonel R. T. Beamish, Lieutenant-Colonel J. G. MacNeece, and Major W. T. Swan.—*The London Gazette*.

Captain W. A. Ward has joined the home district (London) for duty.

Volunteer Corps.

Artillery: 1st Gloucestershire: Surgeon-Major J. S. Carleton to be Surgeon-Lieutenant-Colonel. *Rifle*: 9th Lanarkshire: William Jones Mackinnon to be Surgeon-Lieutenant 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Wallace Ainsworth Pride to be Surgeon-Lieutenant. 1st Tower Hamlets: John Frederick Fitzgerald Parr to be Surgeon-Lieutenant. 2nd Volunteer Battalion the East Yorkshire Regiment: Surgeon-Captain A. F. A. Fairweather to be Surgeon-Major.

Volunteer Medical Staff Corps.

The London Companies: Henry Fulham Turner to be Surgeon-Lieutenant.

Deaths in the Services.

Fleet Surgeon Richard John Barry, R N. (retired), on Nov. 5th, aged 54 years. He entered the service as surgeon in 1871, was promoted to staff surgeon in 1883, and retired after obtaining the rank of fleet surgeon in 1891.

Transvaal War Notes.

At the request of Lord Roberts the Welsh Hospital will remain in South Africa for a further period of three months.

Major S F. Freyer, R A.M.C., Lieutenant-Colonel Johnston, R A.M.C., and Lieutenant-Colonel Harvey, R.A.M.C., have been discharged from hospital to duty.

Food on Board Transports.

Mr. J. Keir Hardy, M.P., sends to the *Times* a complaint from three members of the force ordered from South Africa to China with reference to the food supplied. Among other things they complain of the following, and if a *primâ facie* case can be made out certainly some inquiry into the matter is demanded. "The food given us was bad and insufficient. …… The bread was black, sour, and heavy; the biscuits naturally hard and very oily. The biscuits bore date 1870 …… and some of them bore even an earlier date. …… The salt beef was simply abominable. It is kept in rough-looking tubs and was dated 1873. …… The meat had to be thrown overboard, and we did not receive anything in lieu thereof. …… The accommodation was also limited; two-thirds of the ship was reserved for the officers and sergeants, who numbered in all about 50, roughly, and one-third for the rank and file, non-commissioned officers and men, numbering about 500, and who have the fore part of the ship allotted them, with nowhere to sit or lie down during the day except on the dirty and rusty iron deck."

Mentioned in Despatches.

In the despatches from the general officer commanding in China and Hong-Kong Major Watson, R.A.M.C., is mentioned as having "performed excellent work under great difficulties" The following paragraph also appears: "The medical arrangements for the treatment, care, and removal of the wounded reflected great credit on Major Watson, R.A.M.C., and his subordinates. Not only were those arrangements sufficient for the British wounded, but he was also able to take medical charge of American, French, and Japanese patients and to send them into hospital. Captain Prynne, R A.M.C., and Assistant-Surgeon Pullen, I.S.M.D., were in the advanced fighting line all day dressing cases under fire. They are both valuable officers, always cool and collected."

THE CRISIS IN CHINA.

"For the first time in history the civil medical profession as a whole has had its position officially recognised by the military on a great historical occasion." Thus writes Dr Wykeham Myers, who as representing the whole body of the civil medical profession was granted permission by General Gaselee to accompany the troops in their triumphal march into the Imperial Palace at Pekin. It is gratifying to learn from the *North China Daily News* that Dr. Wykeham Myers will probably be mentioned in despatches for his excellent work when in charge of the wounded after the battle of Yangtsun, when the junk sank in the Peiho at dead of night with 25 wounded on board, all of whom were safely got out by Dr. Myers.

NATIVE AFRICAN REGIMENTS

In the *Times* of Nov. 7th there is a very interesting interview with Dr. G. Douglas Gray, P.M.O. of the British Central African Protectorate, who has just returned from Kumassi having accompanied, as medical officer the force of Central African Rifles dispatched to the Gold Coast. Apart from the usefulness of the coloured man in such cases as the late expedition to the Gold Coast the interview brings out very clearly the great good which the influence of the British officer has upon the character of practically savage native races.

THE NAVAL BRIGADE HONOURS AND PROMOTIONS.

The Queen has been graciously pleased to approve of the following appointment to the Distinguished Service Order: Surgeon Charles Clarke Macmillan.

Fleet-Surgeon James Porter to be Deputy-Inspector-General of Hospitals and Fleets; Staff Surgeon Frederick J. Lilly to be Fleet Surgeon; and Surgeon Ernest O. Lomas to be Staff Surgeon.

UGANDA.

The following telegram has been received at the Foreign Office from Colonel Ternan, Zanzibar:—"Oct. 27th.—Following received to-day from Acting Commandant of Uganda Rifles:—'Fort Ternan, Oct. 21st.—Regret to say that Dr. J. L. Sherlock, Uganda Medical Department, was killed in action with the Nandi on night of Oct. 13th.'"

Colonel Davis, I.M.S., has been appointed Principal Medical Officer of the China Field Force under General Gaselee, Colonel Bookey having vacated his charge in consequence of ill-health.

Correspondence.

"Audi alteram partem."

THE TEACHING OF ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—Your valuable leading article in THE LANCET of Oct. 27th (p. 1215) dealing with the question of the teaching of the art of producing anæsthesia will be welcomed by all who are attempting to give adequate instruction in this subject.

The two points which stand out as the most important are—(1) the absolute necessity for students actually to give the anæsthetic under supervision during their instruction; and (2) the further recognition by physicians and surgeons of the importance of the subject of anæsthetics.

During my own student days the system adopted at my *alma mater* was that the budding anæsthetist stood by the side of the responsible chloroformist or etherist and saw or failed to see, as the case might be, that gentleman's procedure. In most cases he saw nothing, as his attention was riveted upon the steps of the operation. We did not in those days recognise the importance of the study in which we were engaged and were keenly alive to the importance of operative surgery. Systematic lectures on anæsthetics or even demonstrations were not given, so that beyond the most crude notions we had no grip of what we should look for and what to do and what not to do. At the best the attendance was wholly uninteresting and therefore made perfunctorily, whereas now in some hospitals the students actually give the anæsthetics and are asked the reasons for this and that, are made to examine their patients before and after the administration of the anæsthetic, they learn to appreciate that the subject is literally one of vital interest and has a connexion not only with the operation theatre but with the ward—has, in fact, a clinical as well as a practical aspect. They learn that with patients whom they have personally examined and found to show noteworthy departures from the normal a careful choice of anæsthetics has to be made and a definite line of procedure taken. They recognise the phenomena of anæsthesia as they occur and are ready to meet with and combat complications or dangers should such arise. The study becomes a fascinating one if the teacher chooses to show its possibilities, its width and importance. There is, however, the personal equation of the student to be reckoned with. I can usually tell on the first day whether a man will make a satisfactory anæsthetist. The manner in which he holds an inhaler and the way in which he attacks his subject give one a tolerably accurate idea of this. Some never learn and never go beyond the rule-of-thumb stage of giving anæsthetics. These men are always a danger to their patients and their own peace of mind. As you say, much of this failure to acquire the rudiments of their subject is due to the lack of interest taken in the matter by the profession at large and the heads of the profession. When the subject of anæsthetics, using that term as a brief one to connote the science and art of producing anæsthesia, is relegated to a wholly subsidiary position, unrecognised in the curriculum which includes such abstruse studies and arts as practical pharmacy and vaccination, it is not surprising that the lazy and the careless student should absent himself from the classes which teach a non-scheduled subject. At present the individual teacher of anæsthetics may by his personal handling of students infuse enthusiasm, but usually he does so by dint of self-denial and strenuous endeavour and not infrequently in the teeth of cool indifference and even worse from many of those who sit in the seats of the mighty. He is told that the students have too much to think of already, are over-taught and over-examined, and to add yet another subject to their curriculum is to attempt the placing of that last straw which must render laminectomy the only hope of salvation for the camel student. Although most of the ablest surgeons admit the necessity of skilled anæsthetists and many loyally support those of us who are striving to teach our subject as it should be taught, yet many fail to help us and have not cast the slough of those old days when the house surgeon, the ward nurse, or anyone, in fact, was considered a competent chloroformist and was taken with the surgeon "to give chloroform" while he did the operation and "kept an eye on the patient."

Medical men frequently send to us strange messages with patients—e.g., "A B must on no account take 'gas' but may take chloroform," A B being a fit subject for the former, not for the latter. This would seem to show that the anæsthetist is looked upon as a "giver of an anæsthetic." But he should be, and in many cases is, far more. His knowledge of medicine should be adequate to enable him to conduct a most accurate physical examination, including that of the blood and secretions, and his familiarity with surgery should enable him to know what the operator requires and what will be the effect of the operator's manipulations upon the patient under anæsthesia. Again, his knowledge of anæsthetics should be such that he can adapt the anæsthetic to the necessities of the patient and the requirements of the surgeon. Of course, such a counsel of perfection cannot be attained to by the average student, but even he can at least enter the vista at the end of which he may dimly see the possibilities of perfection for which his teacher is daily striving. The tremendous responsibility of the anæsthetist, whose want of knowledge, of skill, or of courage may jeopardise the patient's life or frustrate the surgeon's most skilful endeavours, should be most fully recognised, his facilities for teaching increased, and his place in the system of the hospital training conceded, while his subject should be scheduled and made compulsory. Were this done much would be accomplished and the student of the future would be better equipped than have been many of his predecessors.

I am, Sirs, yours faithfully,

DUDLEY W. BUXTON,
Lecturer on, and Teacher of, Anæsthetics in
University College Hospital.

Mortimer-street, Cavendish-square, W., Oct. 30th, 1900.

"ON THE CONFUSION OF TWO DIFFERENT DISEASES UNDER THE NAME OF RUBELLA (ROSE-RASH)."

To the Editors of The Lancet.

Sirs,—There can be no question that this subject has not received the discussion which its importance deserves. Criticism is always wholesome and necessary in the attainment of truth, but it does not alter facts.

After a close study of rubella now for 30 years, with several hundred cases for investigation, I think that I may claim to know the disease in all its phases when I see it, and I could come to no other conclusion than that two diseases have been confused under its name.

I base my conclusions on these facts:—1. That all four epidemics referred to in The Lancet of July 14th, 1900, were the same disease. 2. That in the epidemic of 1896, where there were two definite diseases, the one was scarlet fever and the other what I then regarded as a variety of rubella. This second disease, occurring concurrently with scarlet fever, proves that it could not be scarlet fever. 3. That the disease is not a variety of rubella but a distinct disease is further proved by the fact that nearly 50 per cent. of the cases occurring in April, 1900, had previously passed through an attack of rubella within a year or more. This makes it clear that there is a "fourth disease" which has hitherto been included under the head of rubella by the profession, myself included.

In reply to my kind critic Dr. C. K. Millard, who raises the question whether the epidemic of 1900 was not after all scarlet fever, I would urge:—1. That I have never seen a case of scarlet fever with a very full rash without having a markedly accelerated pulse, whereas in this fourth disease with the fullest rash the pulse is generally not increased in frequency. 2. That I have never seen a case of scarlet fever with an abundant rash without a marked rise in temperature, whereas in this disease, with the fullest rash, the temperature usually is not raised above 99° F. 3. That I have never seen a case of scarlet fever in the young with a copious rash where the tongue did not peel on the fourth day, whereas in this disease with the fullest rash, which so much resembles the scarlet fever rash as to be, considered alone, indistinguishable, I have never seen the tongue peel. 4. That I have never seen a case of scarlet fever with a very full rash where the skin did not desquamate freely, whereas in this disease I have seen the very fullest rash not followed by any peeling, or the merest dryness of skin. 5. And, lastly, it is scarcely conceivable that were cases of scarlet fever removed from bed after five days, permitted to go out on the eighth day, and, after thorough disinfection on the fourteenth day, regardless of desquamation, allowed to go home to all parts of the country, various sequelæ would not have arisen, and scarlet fever have been spread from one end of the land to the other—even with the few cases I have recorded as the "fourth disease"—were they in reality scarlet fever.

I am, Sirs, yours faithfully,
Rugby, Nov. 3rd, 1900. Clement Dukes.

"APPENDICITIS."

To the Editors of The Lancet.

Sirs,—I am much obliged to Sir Samuel Wilks for his kind letter in The Lancet of Nov. 3rd (p. 1303). The quotations he gives from the writings of Bright and Addison and the references to his own teaching at Guy's will interest, and be appreciated by, all your readers.

I, however, still feel that it is only during the last 15 or 20 years—and I am almost inclined to say the last 10 years—that the profession has fully realised that it is in the appendix itself that probably more than 95 per cent. of inflammatory changes in the cæcal region have their origin. Before this time, I believe, in most minds the appendix occupied the background of the picture, and when a medical man saw a case of "typhlitis" he imagined, in the large majority of cases, an inflammation in and around the cæcum which had started in the walls of this part of the intestinal tract, the appendix being scarcely thought of. Now the appendix occupies the centre and dominating part in the picture, and inflammatory changes originating primarily in the cæcum are relegated to an inconspicuous background.

I am, Sirs, yours faithfully,
Nov. 5th, 1900. H. Littlewood.

THE DURATION OF THE INFECTIOUSNESS OF DIPHTHERIA.

To the Editors of The Lancet.

Sirs,—I should be glad of your opinion as to when a case of diphtheria ceases to be infectious. I take it that if there are no true Klebs-Löffler bacilli to be found on bacteriological examination, then the usual post-card may be sent to the sanitary authority stating that infection has ceased and the house may be disinfected and isolation withdrawn. Again, is it advisable in all cases to have a second bacteriological examination for a negative result?

I am, Sirs, yours faithfully,
Nov. 5th, 1900. T. W. Heywood, M.R.C.S. Eng., D.P.H.

⁂ It is difficult to state with any exactitude when a case of diphtheria ceases to be infectious. Klebs-Löffler bacilli have been stated to have been detected in the mucus of the pharynx six months after the primary attack. As a general rule if six weeks after the disappearance of the membrane no Klebs-Löffler bacilli can be found the usual post-card may be sent. A single examination may as a rule be accepted.—Ed. L.

"PNEUMOCOCCIC PERITONITIS."

To the Editors of The Lancet.

Sirs,—Your annotation in The Lancet of Nov. 3rd (p. 1290) upon pneumococcic peritonitis and the remark that it does not often attract attention in England suggested the following brief reference to two cases which have come under my notice. A girl, aged eight years, was admitted into the Bristol Royal Infirmary in 1899 with acute peritonitis of five days' duration. Abdominal section was performed but no cause for the peritonitis was discovered. She died the following day and at the necropsy no lesion of the abdominal or pelvic viscera or in the bones could be found from which the suppurative inflammation of the peritoneum present could have originated, neither was any septic focus discovered elsewhere in the body. Cover-slip preparations of the pus showed encapsuled diplococci associated with streptococci, and cultures showed the presence of the diplococcus pneumoniæ. In February of the same year a girl, aged 17 years, died in the infirmary from lobar pneumonia complicated by pericarditis. In this case acute peritonitis of a milder type was also present.

I am, Sirs, yours faithfully,
Nov. 6th, 1900. Theodore Fisher.

"THE ETIOLOGY OF RHEUMATIC FEVER."

To the Editors of The Lancet.

Sirs,—The letter of Dr. F. J. Poynton and Dr. A. Paine published in The Lancet of Nov. 3rd, p. 1306, at length does justice to the early observations of British practitioners in the bacterial origin of rheumatic fever, and admits Dr. Alfred Mantle's claim to the honour of being the first to give optical demonstration of the micrococci of rheumatic fever. That Dr. Poynton and Dr. Paine do not corroborate my observations of the existence in the blood of vast quantities of these micrococci at the onset of the disease is also definitely enunciated; it will be my duty to exhibit my proofs at the Pathological Society at the earliest opportunity possible. The stimulus given by the valuable observations of Dr. Poynton and Dr. Paine will no doubt speedily put us in possession of the true facts concerning the origin of this destructive disease.

I am, Sirs, yours faithfully,
Southwick, Nov. 5th, 1900. Edw. F. Grun.

THE TERM "INFLAMMATION" AND THE SUFFIX "ITIS."

To the Editors of The Lancet.

Sirs,—In The Lancet of Nov. 3rd (p. 1288) there appears a paragraph in which, referring to the suggestions of Dr. A. H. Smith of New York, you appear to advocate the disuse of the term "inflammation" and the suffix "itis." May I be allowed to point out a few objections to this course which seem to me to be insuperable? 1. The nomenclature suggested is to be formed by adding the suffix "osis" to the name expressing the agent that causes the disease, but it is not stated how we are to apply this suffix to names such as, for example, "staphylococcus pyogenes aureus" and "bacillus coli communis." 2. A name which has an etiological significance cannot describe a pathological process or an anatomical condition. For instance, the term "traumatosis of bone" will not tell us whether we are concerned with a bruise, a fracture, or a periostitis. 3. If we are to have an etiological nomenclature instead of an anatomical one, we shall not only have to drop the term "inflammation" but also many other terms, such as "fracture," "abscess," "hypertrophy," &c. 4. If a purely etiological nomenclature is adopted it will have the effect, contrary to the statement in the paragraph referred to, of diverting the attention from the patient to the disease, since it will imply that the only cause of the disease is that which is expressed in the name, and that, in consequence, the only method of treatment is to remove this cause, whereas many of the most successful methods of treatment at present in use have for their object the improvement of the general condition of the patient so as to enable him to combat the disease. 5. Inflammation is a distinct pathological process, as distinct, in fact, as hypertrophy or atrophy, and has a definite object, and that object is to remove or neutralise the irritant. If this fact were properly appreciated it would be an immense advantage to medicine. 6. If we are to do without the term "inflammation" and the corresponding suffix "itis," how are we to describe a condition like fibrinous pericarditis, since exactly the same condition may be caused by many different causal agents? Lastly, the term "tuberculosis" is cited as a precedent. Surely a more unfortunate precedent could not very well have been found. The name "tuberculosis" was given to a disease which was characterised by a definite anatomical lesion—the "tubercle." Since the discovery, however, of the tubercle bacillus the term has been divorced from its anatomical (and true) meaning and now has a purely etiological significance, with the result that diseases which would have been rightly included in the old sense of the term are now assigned the unsatisfactory term "pseudo-tuberculosis," and the form of inflammation which used to be called "tubercular" is now termed "nodular." Similarly, if other terms are altered in the same way and an etiological nomenclature is adopted we may expect a like confusion to be the result

By all means let us have an etiological nomenclature and, if necessary, let us apply the terms "traumatosis," "streptococcosis" (not "traumosis," "streptocosis") to diseases caused by the respective agents, but this system can never replace an anatomical nomenclature such as is implied in the suffixes "itis," "oma," &c Both systems are necessary, but neither can take the place of the other.

I am, Sirs, yours faithfully,

Charles Powell White, M D Cantab., F.R C S. Eng

Medical School, Leeds, Nov. 6th, 1900

THE ETIOLOGY OF CANCER.

To the Editors of The Lancet.

Sirs,—A patient of mine is thinking of investing a sum of money for the purpose of stimulating investigation into the etiology and cure of cancer Would some of your readers kindly assist by giving their ideas on the subject?

I am, Sirs, yours faithfully,

Nov. 6th, 1900 T. S. F.

Notification of Phthisis.—At the meeting of the Bath Sanitary Committee held on Oct. 29th the sub-committee recommended the voluntary notification of phthisis, with the usual fees for such notifications.

Municipal Elections and Medical Men in the West of England—As the result of the recent municipal elections Mr. Colston Wintle, M.R.C S. Eng., L R.C P. Lond., was elected at Bristol; Mr. W. Hadwen, M.D. St. And., L.R C.P Lond, M.R.C S Eng., at Gloucester; Mr. G. A Rae, L R.C P, L R C S., L.M. Edin., J.P., at Devonport; Mr. Elgar Down, L R C P. Lond., M.R C S. Eng., at Stoke, Plymouth; Mr E J Domville, L R.C.P. Lond., M.R C.S. Eng., at Exeter; Mr G M Winter, L R C.P. Lond., M R C.S. Eng, D.P.H. Camb, at Torquay; and Mr. R. V. Sutton, L.R C P., L.R C S Edin., L F P.S. Glasg., at Newport, Mon.

THE UNIVERSAL EXHIBITION OF PARIS.

(From our Special Correspondent.)

(Continued from p. 1311)

The Pasteur Saloon.

There was a hitch with regard to the French sanitary exhibits. In the various financial calculations made no special credit was voted for a French sanitary section. This gave rise to protests, prolonged negotiations, and loss of time. But beyond the fact that this occasioned a regrettable delay the question was finally settled in a satisfactory manner. The money was forthcoming and a special building was erected on the banks of the Seine, opposite the Press Pavilion and at the extreme eastern end of the gallery for the Army and Navy exhibits. Thus, by a sort of logical sequence, the French sanitary section merges into the French military, medical, and ambulance services which precede the purely military exhibits. The building commences with an ornamental tower. The circle is divided into four parts and in the centre there is an ornamental case surmounted with the bust of Pasteur. This, the Salon Pasteur, conveys in a small space and in compact form instructive indications of some of the most beneficent discoveries of the nineteenth century. In the centre there are relics of the great investigator and teacher. Here are the instruments, the flasks for culture broths, the microscopes, the now old-fashioned and very simple implements with which Pasteur himself worked, which he handled for many long years and to such good purpose. The bottles which he had filled and re filled stand there as silent motionless witnesses. And there are little bits of paper, so insignificant in themselves and yet so eloquent, for on these Pasteur, with his own hand, rapidly scribbled down the simple unpretentious record of his laboratory observations. They relate to his studies on rabies. It is easy to note with what method, deliberation, tidiness, and order this master mind proceeded in his investigations. First there is the indication of the method to be followed, then underneath, in a very small, neat, and legible handwriting, there is a brief account of the results of the experiments, of the fate of the inoculated animals and their symptoms, and then, well detached from the rest, are the conclusions arrived at.

The case under the bust of Pasteur is placed horizontally so that the visitors can bend over the glass and examine the contents of its eight compartments. Here the whole work of Pasteur is set forth as it were in eight chapters. In the first compartment there are models of crystals made by Pasteur himself, labeled with his own handwriting, and some of the crystals themselves in the very bottles where he placed them many, many years ago. In those days he was studying pure chemistry and established the existence of asymmetric arrangements. From this grew the idea that the molecules formed in space a geometric body with three dimensions. The study of this crystallisation led to the study of ferments and to the discovery that ferments were living organisms. This phase is shown in the second compartment. Then comes the contest against the believers in spontaneous generation set forth in the third division. Here the little balloon-shaped bottles show the proofs given by Pasteur, for there is also his apparatus for purifying the air by heat and method of filtering it, so that no fermentation took place when the air was sterilised. Then there are bottles which were opened on the summit of the Montanvert in 1860 and which to this day remain perfectly sterile The next two compartments show how these discoveries were applied to the preservation of wine and to preventing the spread of disease among silkworms. The sixth compartment deals with the germs of the atmosphere and here is the very simple, almost rudimentary, but effective apparatus which Pasteur devised so as to destroy all living organisms in the atmosphere. Pasteur was now beginning to study animal pathology and then he took up the discovery of the bacteria of anthrax, made in 1850 by Devaine and Rayer, and in the seventh division is shown how this idea of the living virus was applied to other diseases. Here are test-tubes containing the blood of animals suffering from anthrax and the method of isolating and of attenuating the virus. Here is a rabbit inoculated with rabies, the spine being exposed; there are specimens of anti-rabic vaccine, and among these samples of the way these studies were pursued is the following laconic note: "Number of cases treated in 13 years, 21,631; died, 99; mortality percentage, 0·45." Over these glass cases crowds of people bend reverently. They look at the strange things here shown, in themselves so little to look at, and they try to understand. Peasants from the country in their native costumes, simple town and country folk, most of them quite ignorant, utterly unable to grasp the meaning of what they see, and yet all spellbound by the word written above—Pasteur. It is astonishing how long they will tarry, how they will strain to read some inscription, striving, longing to understand; and then how grateful they are if anyone is able and ventures to give a little explanation. The explanation, however, must be brief or there would soon be such a crowd as to cause serious inconvenience. It is indeed an edifying sight to see daily these crowds of poorer visitors, simply dressed, but always neat and tidy, throng into the Pasteur Saloon. Perhaps no better homage could have been rendered to this great *savant* than the sincere respect shown by the masses for his noble work. However vague their conceptions of bacteriology they displayed wonderful interest and anxiety to know more, and it does credit to the French people that so many of the poorest classes should care to tarry so long in this highly scientific section of the Exhibition.

On each side of the main entrance there are shelves loaded with bottles. These contain gelatin in which colonies have been planted so as to form designs. Some are red, others are yellow or violet, and spell out the names of Pasteur's pupils, such as Roux, Chamberland, &c. These microbe cultures are not repugnant in appearance; some of them, are rather pretty like mushroom growths, and yet they represent pneumonia, plague, cholera, tuberculosis, and other diseases. Then there is a case containing illustrations of the researches of Behring and Roux on diphtheria, and Calmette's anti-venom serum for the bites of reptiles and vipers. The latter come from the Pasteur Institute of Lille.

Foreign Nations in the Pasteur Saloon.

The idea was to collect from all nations whatever testimony was available to show the results of the applications of Pasteur's theories in these various countries. This, however, was undertaken too late, so that the response has been incomplete. Nevertheless, those nations that have answered the appeal were sufficiently numerous to constitute a fairly good exhibition. On entering, and to the left, there is the exhibit that Austria has sent. This comprises fine large photographs of bacteria from the Hygienic Institute of the Vienna University. These include full details of the five cases of plague that recently occurred at Vienna. There are photographs of the patients showing the buboes, two of which have ulcerated. The Sero-therapeutic Institute of Vienna and the Anti-rabic Institute at the Rudolfstiftung Hospital also send specimens. There are many large coloured photographs and drawings of the microbes of plague and statistics as to the immunisation of horses, plans of hospitals, and the means employed for preparing serum, vaccine, and the like. Immediately opposite Germany has a splendid exhibit and the wooden model of the Gesundheitsamt has gained the Grand Prix. Here are a great number of statistics and various methods by means of coloured cubes and cones for showing how epidemic diseases have decreased by the use of antitoxin, vaccine, and similar preparations. Thus two brown cones marked D represent the reduction of deaths from diphtheria observed in Germany since the introduction of anti-diphtheritic serum. During the years 1892 and 1893 in the six states contributing to these statistics 113,259 children from one year to 15 years of age died from diphtheria. Then began the use of anti-diphtheritic serum, and in spite of the increase of population the deaths from diphtheria among children of these ages during 1896 and 1897 only amounted to 45,942. Thus the height of the two cones, which have the same diameter at the base, is in the proportion of 7 to 3.

The third side of the room contains the information forwarded from Italy and Switzerland. This includes a large map indicating the distribution of malaria over the Italian peninsula and enlarged photographs of the mosquito that conveys the germ. There are also charts showing for each month of the year the quarters of Rome that are most affected by malaria. Tables indicate how the use of antitoxic serum has increased in Italy and that the total mortality, which for the entire kingdom amounted to 29·5 per 1000 of the population in 1887, was only equal to 22·2 in 1897 and 23·1 in 1899. Switzerland sends photographs of the popular sanatorium for the treatment of tuberculous patients at Heilingenschwendi and diagrams showing the mortality from phthisis at various ages. The maximum number of deaths among females from this cause occurs from 14 to 19 years of age, while among males it is from 20 to 30 years of age. Then there are very good coloured maps indicating the prevalence of different diseases in various parts of Switzerland, including phthisis. From these it will be seen that from 1876 to 1886 there was an average of 53 deaths per annum per 100,000 inhabitants of the large towns caused by typhoid fever, and that the proportion for all Switzerland, including the towns, was 37 per 100,000. From 1896 to 1899 the proportion of deaths from typhoid fever was only 11 for the large towns and nine for all Switzerland per annum per 100,000 of the population. Undoubtedly these are figures that will not fail to encourage nervous tourists.

Typhoid Fever in French Towns.

On the fourth side of the Pasteur Saloon the French Ministry of the Interior exhibits equally interesting diagrams. They also show how typhoid fever has been reduced in the towns of France which have more than 30,000 inhabitants. One of the worst among these towns is that of Havre. Here the deaths from typhoid fever were equal to 180 per 100,000 per annum from 1886 to 1890. The proportion fell to 140 per 100,000 from 1891 to 1895 and to 40 from 1896 to 1898. The other towns that stand high on the list are Lorient with 200, 70, and 90 deaths per 100,000 population per annum for the three same periods—namely, from 1886 to 1890, from 1891 to 1895, and from 1896 to 1898. Calculating in the same manner for the same periods there were 70, 50, and 100 deaths annually from typhoid fever at Troyes; 140, 30, and 40 at Angoulême; 50, 30, and 30 at Nice; 60, 100, and 90 at Toulon; and 80, 50, and 60 at Marseilles. The towns of Cette, Béziers, Perpignan, and Toulouse are about as bad; but, nevertheless, these diagrams as a whole show a general reduction in the prevalence of fatal cases of typhoid fever. There are similar tables given dealing with pneumonia, acute bronchitis, diphtheria, and other diseases. The two first mentioned remain about stationary, but there is an immense reduction in the death-rate from diphtheria, and the result for many other diseases is eminently satisfactory. Such is the general character of the exhibits in the Pasteur Saloon. They constitute a well-deserved tribute to the great French *savant*, and it is only to be regretted that other nations were not able to contribute their quota of information.

Paris, Nov. 4th.

LIVERPOOL.

(From our own Correspondent.)

Liverpool School of Tropical Medicine: Return of Dr. H. E. Annett from West Africa.

Dr. H. E. Annett, of the Liverpool School of Tropical Medicine, returned to Liverpool last week after a tour of investigations in West Africa extending over eight months. Dr. Annett studied the conditions of tropical diseases over an area embracing 1000 miles of the coast, extending his researches to Lokoja on the river Niger. He has accumulated a mass of observations on the relations between malaria and the situation, the geographical peculiarities, and the temperature. In the main these data bear out the theory already established by the inquiries of Major R. Ross, late I.M.S., and Dr. R. Fielding-Ould that malaria is disseminated by the anopheles mosquito.

University College, Liverpool: Old Students' Association.

The first annual dinner of the Old Students' Association was held on Oct. 27th, Dr. John Hill Abram, the president, being in the chair. The toast of "The Association" was proposed by Principal Dale, who cordially welcomed the association as a means of maintaining the active interests of old students in the welfare and development of University College. Dr. Abram, in reply to the toast, said that the progress already made in the organisation of the affairs of the association and the number of members enrolled were most encouraging. He emphasised the necessity for a students' union and club-house to which old students might resort when revisiting the college He also expressed the hope that at no distant date Liverpool would have a university of her own, thus identifying her students with the city

Municipal Eccentricities

The mode of procedure of the Selection Committee of the City Council has given rise to much comment both in the lay press and in medical circles Among the new members elected to the City Council on Nov 1st were Mr William Permewan, a Doctor of Medicine of the London University, a Fellow of the Royal College of Surgeons of England and a Diplomate in Public Health of the University of Cambridge, and Mr Muirhead a respectable fish and poultry dealer As Dr Permewan had defeated a member of the Health Committee his name was proposed to fill the latter gentleman's place on the committee Dr Permewan's friends were coolly informed by Alderman Petrie who took a leading part in the management of the affairs of the Selection Committee, that Dr Permewan must begin at the bottom of the ladder and abide his time for a seat on such an important committee as that of public health The hollowness of this statement is revealed by the fact that Mr Muirhead also a new member of the council, was placed on the Health Committee to the exclusion of Dr Permewan whose admitted knowledge of matters connected with public health would have been a needed accession of strength to the deliberations of that committee The whole proceedings may be summed up as childish in the extreme, and evincing little regard by the Selection Committee for the public weal

Medical Visitor of Licensed Houses in Lunacy

Dr James Barr, honorary physician to the Royal Infirmary, has been re appointed by the city justices medical visitor of licensed houses for the reception of lunatics within the city of Liverpool in pursuance of the Lunacy Act, 1890

The Royal Albert Asylum, Lancaster

The thirty sixth annual report of the central committee stated that there were 593 patients in the institution 265 belonging to Lancashire, 166 to Yorkshire 54 to Cheshire, 49 to Durham, 28 to Cumberland, 13 to Westmoreland, 13 to Northumberland, and five to other counties The general income had been well sustained the principal items being maintenance account £21 683 sustentation fund (endowment) account £5256 and extension fund £10,935, including the Ashton Wing The munificent donation of £10 000 from Lord Ashton had been devoted to the building fund of the new wing During the year £2962 had been collected by the several ladies' associations The Ashton Wing will accommodate 100 additional patients There had been 74 admissions during the year, 58 discharges, and 11 deaths The average number resident had been 594 The patients admitted were not below the average in intelligence and physical condition of the patients previously received The asylum is not a mere asylum in the sense of being a refuge and home for hopeless cases but a training institution aiming to develop the dormant physical and mental powers of the inmates, to improve their habits, to cultivate their moral and religious feelings, and to train them in some useful industrial occupation, so that when leaving the institution they might be less burdensome to their friends, and if possible, contribute something towards their own maintenance An alteration in the title of the institution was approved, adding the explanatory sub-title "A Training Institution for the Feeble minded as an affix to "the Royal Albert Asylum"

Proposed Sanatorium in Flintshire for Phthisis

It is proposed to erect a sanatorium in Flintshire for the treatment of patients suffering from phthisis The scheme owes its inception to Mr W J Crossley of Manchester, who, it is understood, will not only erect the buildings at his own cost, but will also endow them The locality selected lies between Halkin and Rhydymwyn on the estate of the Duke of Westminster near Moel Gaer, a commanding mountain The scheme provides for the erection of a large central residential building for the patients and a number of small bungalows on the south west slope of Moel Gaer, to which the patients will proceed in the daytime in order to gain the full benefit of the pure mountain air It is also proposed to plant the place throughout with pine trees another essential to the treatment of tuberculosis on the open air system

Death from eating Putrid Meat

Mr J O Bate, coroner for West Cheshire, recently held an inquest into the circumstances affecting the death of a police constable who died during the previous week in consequence, it is alleged, of having eaten some diseased meat whilst engaged on special duty with other constables at Altrincham during the election The deceased partook of some beef which some of the constables alleged was tainted The deceased became ill that night and complained of pains in the region of the stomach Mr A H Godwin of Liscard was called in to see him on the following morning, Oct 12th, and found him suffering from symptoms of irritant poisoning Peritonitis subsequently supervened from which he died on Oct 18th Evidence was given by the caterer of the meat that the joint, being a large one, was put into the oven on the afternoon that he received it (being apparently perfectly sound) and partly cooked It was then taken out and left to cool and at midnight it was put into an ice chest where it remained all night Next morning it was cooked finally and at noon it was sent away to be served to the constables A second constable, who had also partaken of the beef, became suddenly ill but recovered No ill effects from eating the meat had resulted to the remainder of the constables The jury found a verdict that "Death was due to peritonitis caused by eating putrid meat" They were of opinion that the method of cooking and cooling the meat was at fault

Nov 6th

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Edinburgh Health Society

THE opening lecture of the present course of lectures of the Edinburgh Health Society was delivered on Saturday night in the Oddfellows' Hall, Forrest road, by Dr Leslie Mackenzie, medical officer of health for Leith The subject of the lecture was 'Public Health and Individual Duty' Dr Mackenzie considered what the meaning of the public health movement was, pointing out that it was essentially an ethical service based on the principle that to forward human happiness was human duty He considered that the fundamental doctrine in the theory of public health was that man was capable of variation of growth, of development, and of integration Man gained in strength as he gained in opportunity, and to free him from entanglements was to lessen for him the burden of his inheritance of evil and to strengthen for him the gift of his inheritance of good And that was the ultimate ground of public health practice, which claimed primarily at clearing the way for the free development of the human organism

A Proposal to Appoint a Port Medical Officer for Glasgow

At a meeting held in the National Hall, Gorbals, on Monday last, in the interests of a candidate for the representation of one of the municipal wards of the city, Dr Thomas Colvin who presided made special reference to the recent visitation of plague and advocated the appointment of a port medical officer in Glasgow with duties similar to those of Dr W Collingridge in the Port of London

Aberdeen University

The fifth annual meeting of the Aberdeen University Students' Union was held in the debating hall, Marischal College, on Oct 27th A satisfactory report on the finances was submitted Major Manuell (medical) has resigned the office of president, as his connexion with the University as a student is to cease Mr G O Gould was appointed as his successor and other office bearers were also elected —The University Choral and Orchestral Society have elected Professor Japp LL D (chemistry) as president for the ensuing year Eight bursaries from £22 10s to £18 per annum have been allocated to medical students

Nov 7th

IRELAND.

(FROM OUR OWN CORRESPONDENTS)

Abattoir Reform in Dublin

THE Corporation of Dublin a short time since sent two of its members Mr Kennedy and Mr Clancy, to visit Hamburg, Munich, and other towns in order to inquire into the working of Podewill's system for the destruction of slaughter-house offal. Their report is of interest, more especially when one recalls the justly adverse criticism of the slaughter-houses of Dublin by the Sanitary Commissioner of THE LANCET who visited the city some months ago. The offal-utilising method followed in Munich is described as a source of considerable profit to that municipality, the fat being sold for 22*s.* per cwt. and the manure at £5 per ton. Dresden, which boasts of having the most perfectly equipped abattoir as yet constructed, was visited, and the details of the Podewill system as used there are fully described. To put the matter shortly, the offal from diseased and slaughtered animals is—after the fat has been removed automatically—reduced to a powder which is found to be valuable as a food for pigs and fowls. To equip the city abattoirs in Dublin with the Podewill apparatus will cost about £5000. The writers of the report allude to the precautions taken by the municipal authorities in continental towns against the sale of infected meat. There are no private slaughter-houses and no meat is permitted to be exposed for sale unless it bears the brand of the public abattoir at which it was killed and dressed.

Dublin Sanitary Association.

The council of the Dublin Sanitary Association met on Nov. 1st, and received a letter from Sir Charles Cameron stating that the Public Health Committee had recommended the Municipal Council to make tuberculosis of the lungs a notifiable disease for one year as a tentative measure.

Return of the Staff of the Irish Hospital from South Africa.

The Royal College of Surgeons in Ireland has decided to entertain Sir William Thomson and his colleagues of the staff of the Irish Hospital at a dinner to be given in the College on Nov. 24th.

City Hospital for Diseases of the Skin, Dublin.

The first annual meeting of the friends and supporters of this hospital was held at the institution on Nov. 1st. The meeting was large and enthusiastic. Letters of regret for non-attendance were received, inclosing cheques, from many representative citizens Sir Francis Cruise, consulting physician to the hospital, was unable, owing to an urgent professional call, to be present. Mr. Thomas Myles, President of the Royal College of Surgeons in Ireland and consulting surgeon to the hospital, Sir Charles Cameron, and Mr. A H. Jacob were also, owing to a council meeting at the Royal College of Surgeons in Ireland at the same hour, unable to attend, but they bestowed upon the meeting their imprimatur; Dr. C. M. O'Brien, physician to the hospital, epitomised the work of the institution during the year. 2000 patients had been registered, of whom many were cured and all were relieved. He said that the expenditure exceeded the income from all sources during the year and in this the governors had the sympathy not only of the meeting but of the citizens at large Dr G B. White, surgeon to the hospital, concurred with his colleague Dr. O Brien. Alderman Ireland, J.P., representing the corporation, warmly approved of the objects of the hospital and the good work done there. He himself would be in favour of giving a grant from the corporate funds and he felt sure that when the good work of the institution was made known to his fellow-members they would support him.

The Belfast Union Fever Hospital

As anticipated in THE LANCET of Oct. 27th, p. 1240, Dr. A. G Robb has been appointed physician to the Belfast Union Fever Hospital in place of Dr. E. C. Bigger, who has been appointed Local Government Board inspector.

Queen's College, Belfast.

The following medical scholarships, &c., were awarded at the examinations held at the commencement of the session in the above college. Fifth year: Medicine and pathology, Albert Lytle Black, B.A.; surgery and midwifery, David M'Mordie, B A. (John Armstrong, a prize) Fourth year: Henry Mulrea Johnston and Sydney Herbert George Blakely. Third year: Thomas Lyle and Daniel Gillespie. Second year: William James Wilson and Robert James Spence. First year: Literary, James Stuart Dickey; science, Robert Jamison.

Ulster Medical Society.

The first meeting of the session 1900–1901 was held on Nov. 1st in the Belfast Museum. Professor J. W. Byers, ex-President, occupied the chair, and after the minutes were read he introduced the new President, Professor W. H. Thompson of Queen's College, Belfast, who delivered his inaugural address. After thanking the members for electing him Dr. Thompson gave a most interesting account of recent advances in our knowledge of normal digestion, based largely on the work done in Pawlów's Laboratory in St. Petersburg. In conclusion, Dr. Thompson regretted the inadequate teaching of students in physiological chemistry and spoke of the meagre attempts made by the English nation to provide laboratories for the study of such subjects as were being constantly investigated in kindred institutions in Europe and America. Professor J. A. Lindsay, in proposing a vote of thanks to the President, referred to the excellent laboratories which he had visited in the Johns Hopkins University in Baltimore. Dr. Dempsey, J.P., seconded the vote of thanks, which was acknowledged by Dr. Thompson A report from the council in reference to the publication of the Transactions having been considered it was arranged that the annual dinner should be held on Saturday evening, Feb. 23rd, 1901.

Health of Belfast.

In a report presented to a meeting of the city corporation on Nov. 1st it is stated that the death-rate for the week ended Oct. 6th had been from all causes 18·9 per 1000, and from the principal zymotic diseases 3 5. In the corresponding period of last year the general death-rate was 26·1 per 1000 and that from zymotic diseases 4 5. The deaths from zymotic diseases, as also those from chest affections, are much less numerous than they were in the corresponding period of last year. Both in the number of cases of typhoid fever notified, as well as in the mortality, the disease seems to have subsided into the ordinary endemic condition which appears now to be a constant factor in Belfast.

The Irish Medical Association.

On Nov. 1st a meeting of the members of the Irish Medical Association residing in co. Antrim and co. Down was held in the Belfast Museum. Dr. W. A. McKeown occupied the chair, and it was unanimously decided to invite the association to hold its annual meeting in Belfast in June, 1901. The headquarters of the society is in London, but a new departure was made a few years since when the annual meeting was held in Cork, and in the coming year this experiment is to be repeated and the society is to meet in Belfast The association is largely concerned with looking after the interests of the Poor-law medical officers in Ireland.

The Spread of Infectious Disease

At a meeting of the Portadown Town Council on Nov. 5th Dr. J. L. Rowlett, the medical officer of health, reported that during the last month there were six cases of scarlet fever notified, one of diphtheria, and one of puerperal fever. He had considerable trouble in isolating one case of scarlet fever. The patient, who was found to be "peeling," was running amongst the children who were attending school, and it was only when presented with a magistrate's order for her removal to hospital that the parents consented to have her properly isolated.

The Annual Dinner of the City and County of Cork Medical and Surgical Association.

The annual dinner of the above association was held in the Victoria Hotel, Cork, on Nov. 3rd. The President (Professor Henry Corby) occupied the chair, and amongst the guests were the Lord Mayor (Sir Daniel Hegarty), Professor Hartog and Professor Stokes of the Queen's College, representatives of both branches of the legal profession, besides several leading citizens identified with the trade and commerce of the city. The first toast was "The Queen," which was duly honoured. Then "The City Corporation" was proposed by the President, who referred to the improved sanitation of the city. The Lord Mayor and Sir John Scott responded and dwelt on the valuable aid which the corporation had at all times received from members of the medical profession when any projects calculated to improve the health of the citizens were under discussion. Sir John Scott, in proposing the toast of "The Cork Medical School," alluded to the brilliant array of medical graduates who had received their training in Queen's College, Cork, and said that not only the medical men of Cork, but the citizens generally, had reason to feel proud of such achievements. Professor Hartog and Professor

W. E. A. Cummins responded, the latter stating that recently when paying a visit to Netley he was astonished on consulting the lists to find that such a very large proportion of army surgeons had been educated at the Cork College. "The Legal Profession," proposed by the President, was responded to by Professor Stokes, Mr. George Crosbie, and Mr. Exham, solicitor. The President, in proposing "The Navy and Army Medical Officers," referred to the invaluable services rendered by these gentlemen in the South African war and said that it was a source of pride to the medical profession to know that the percentage of members of the Royal Army Medical Corps who had won the Victoria Cross was far higher than that of any other branch of the Services. The Lord Mayor in proposing the toast of "The City and County of Cork Medical and Surgical Association" alluded to the advantages conferred by the association on the local members of the profession, and through them on the citizens generally. Dr. Giusani responded in an able speech. Mr. E. W. Allsome proposed the health of Dr. J. J. Tracy, the honorary treasurer to the association, and laid stress on the invaluable services rendered by Dr. Tracy to the profession in connexion with the "battle of the clubs" and said how gratified all were to find that Dr. Tracy was again restored to health. Dr. Tracy responded and referred in grateful terms to the testimonial which had been presented to him when he had been in bad health and said that he valued it highly as an expression of the kindly feelings of his medical brethren. The toast of the health of Dr. R. P. Crosbie, the honorary secretary, was warmly received, and Dr. Crosbie, in reply, said that it afforded him very great pleasure to have had any part in making the evening's proceedings so successful. Mr. P. J. Forde proposed a vote of thanks to the President. Dr. Corby, in replying, referred to the great honour that the association had conferred on him by electing him president for the second time. A pleasing innovation was the presence of two lady practitioners. There were several songs in the intervals between the speeches, and the evening was in every sense a most enjoyable one.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Epidemic Disease in France during 1899.

AT the meeting of the Academy of Medicine held on Oct. 16th M. Laveran read the annual report upon the epidemics which have prevailed in France during 1899. According to him the documents upon which the report is founded are very incomplete. Throughout the departments the medical men employed during epidemics lose heart and are unable to collect sufficient exact information. The colonial reports come chiefly from M. Kermorgan and M. Matignon and deal with the plague in Madagascar and China. The report concluded with the following recommendations. 1. A special commission should be appointed to re organise the department which has to deal with epidemics. 2. Measures should be taken to insure the accurate declaration of epidemic disease. 3 All mayors should be asked to see that the cause of death is stated on the certificate of death. 4. Schoolmasters and schoolmistresses should at once notify any case of infectious disease among their pupils 5. They should also insist that no child who has suffered from any infection should be allowed to return to school until after a sufficiently long period of convalescence 6. Infantile diarrhœa should be tabulated separately from other kinds of diarrhœa in the statistics. 7. Statistics of disease should be regularly kept in every commune and upon one uniform plan 8 Disinfection should be much more widely used than at present and measures for the same should be able to be taken by those outside the ranks of professional disinfectors. Various other recommendations treated of general hygiene, of the isolation of soldiers suffering from infectious disease, of pure water-supplies, and as to adding to a sum of 300 francs which has been placed at the disposal of the Academy of Medicine to defray the expenses of publications dealing with infectious diseases.

The Aggravation of Cases of Typhoid Fever owing to the Vicinity of a Crèche.

Dr. Renon has recently drawn attention to a remarkable instance of intensification of the virulence of typhoid fever as treated in a hospital. His paper was read before the Hospitals Medical Society and the theory therein put forward is certainly startling, but nevertheless his figures deserve very careful consideration. They dealt with a series of cases of typhoid fever in which the patients were warded next door to a crèche, that is to say, a ward where women were taken in accompanied by their children. Between July 15th and Oct. 1st Dr. Renon had under his care at the Necker Hospital nine cases of typhoid fever, which were distributed between the crèche and the women's ward in the Peter block. Of these nine cases he lost four, or 44 per cent. These women, who were admitted with typhoid fever of a mild form, suddenly developed intense aggravation of the symptoms after about six days. Prostration was intense and they had constant vomiting and refused their food. Of the five patients who recovered only one maintained the mild type of disease, the other four exhibiting the gravest symptoms. These figures could not be put down to the fact that the women were nursing for only three of the nine were nursing and were warded in the crèche while of these three only one died. The six other cases were not those of nursing women and they were not warded in the crèche but in the women's ward. Of these six three died. Treatment, nursing, and a severe type of epidemic could all be excluded, for in the other wards of the hospital where the treatment and nursing were the same, the mortality was very different. Besides, the previous mortality from typhoid fever in the Peter block had been considerable, namely, seven out of 14, or 50 per cent. During the present year up to Oct. 1st, the mortality in this block from typhoid fever had been 11 out of 19 or 57 per cent, while at the same time in the other blocks the mortality among the women was five times less. The Peter block is therefore responsible for this enormous mortality and it is logical to infer that the proximity of sucklings plays a prominent part. Various forms of enteritis are common in the crèche and despite every care it is only natural that the different organisms of infantile diarrhœa exist in enormous numbers both in the crèche and in the adjoining ward. Probably, therefore, the patients suffering from typhoid fever are infected secondarily by microbes from infantile diarrhœa.

Operative Asepsis.

At the meeting of the Society of Surgery held on Oct. 24th M Walther gave a short account of the researches which he had lately undertaken upon this subject from a bacteriological point of view. The work had been done in the laboratory of M. Widal, in collaboration with him and his assistant, M. Ravaut The technique was as follows. Bouillons were sown with scrapings from the hands, which had been previously cleansed as follows. They were first soaped and brushed for 10 or 15 minutes in a small quantity of water which previously boiling had been allowed to cool until it could be borne. This water was changed four or five times. The hands were then soaked in alcohol, then in sublimate solution, then again in alcohol, and finally, to remove any trace of sublimate, in a fresh supply of hot water. They were then dried with hot sterilised compresses. Of 19 "sowings" (*ensemencements*) done before the operation and immediately after the washing one only gave any positive result Of six done during the operation only one gave rise to a culture. Three trials made after the operation gave a negative result. Trials were also made with scrapings from the skin of the patient which gave negative results in five instances and a positive result in one M. Walther concludes from these results that absolute sterilisation of the hands is possible in the great majority of cases. Indiarubber gloves are most inconvenient, especially as regards movements of prehension, so that, to take an instance, in the operation for radical cure of hernia, dissection of the sac is almost impossible for the surgeon while wearing these gloves.

Nov. 6th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Medical Attachés to German Embassies.

SOME Berlin periodicals, in discussing the possibility of an outbreak of plague in Europe, propose that medical attachés should be appointed to the German embassies abroad and should be assigned the duty of studying the hygienic conditions of the countries where they happen to be stationed and of promptly informing the German Government of the occurrence of cases of infectious disease. The arrangements should be settled by international agreements and in this way international regulations for the notification and prevention of epidemic diseases might be put on a more satisfactory footing than at present. Precedents already exist for embassies having attachés charged with other than diplomatic functions, because agricultural experts, architects, and engineers have for many years held appointments in connexion with the German embassies in order that they might inform the Government of anything remarkable happening in their respective branches in foreign countries. The position of the medical attachés would be analogous to that of the other technical attachés.

Post-Graduate Instruction.

The civilian members of the medical profession have often felt disappointed when the ample means at the disposal of the Army Medical Department for the post-graduate instruction of army medical officers were compared with the opportunities afforded for the same purpose to the civilian medical officers of health or even to general practitioners. Courses of instruction provided at the expense of the Treasury are available for members of the army medical staff during nearly the whole time of their service and in this way they are kept informed of the progress of medical knowledge. General practitioners, on the other hand, if desirous of engaging in post-graduate study must go to a university during their holidays and pay the rather high fees charged for post-graduate lectures. A wide-spread desire has therefore for a long time been expressed that the Government should establish post-graduate courses free of charge for civilian practitioners and the Government has at last complied. The Minister of Public Instruction has consequently arranged for the delivery of a series of lectures in the Charité Hospital by professors of Berlin University to members of the Berlin medical profession only. The first séries was delivered last spring, the subject being Tuberculosis, its Prevention, Bacteriology, Treatment, Complications, &c. The second series has been appointed for October and November and will deal with venereal diseases, including syphilis. The lectures are given in the evening five times a week in order to allow medical practitioners to attend after their day's work is done. That these lectures have really met the requirements of the medical profession was shown by the fact that all the tickets were applied for the day after their issue. In the inaugural address the director of the Charité Hospital pointed out that post-graduate lectures on practical topics like the present were a necessity for the general practitioner, because the increasing amount of medical literature and the great number of new therapeutic methods made it impossible for busy practitioners to keep abreast of the progress of medicine by reading only. Similar lectures will take place in other towns also, so that practitioners throughout the country will have opportunities of improving themselves without being compelled to interrupt their practice and to pay high fees. The above-mentioned official lectures must not be confounded with those of the Association for Post-graduate Study (Docenten Verein fur Ferien-Curse), where everybody is admitted who pays the fees and where opportunities for practical work, examination of patients, operations, &c., are afforded.

A Medical Strike Fund.

A committee of medical men in Leipsic, under the presidency of Dr. Hartmann, has addressed an appeal to all medical practitioners in Germany to unite in collecting a large strike fund. In the letter sent by these gentlemen it is said that the scanty remuneration of the profession in this country is due especially to the dominant position of the sick clubs These clubs, which in Germany are official institutions, membership of them being compulsory for working people, are in the habit of paying their medical officers very badly and of appointing them on humiliating terms The complaints against this state of things are manifold and are as old as the present workmen's insurance laws Many methods for the redress of these grievances have been proposed and strikes have even occurred in different places, as at Remscheid and at Iserlohn. The above committee wish to organise a strike of medical officers to clubs on a great scale, and with this object in view invite medical men to become members of the new medical union. Members are to pay one mark (=1*s*) a week, and the leaders of the movement hope to collect a sum of 2,000,000 marks (=£100,000) to begin with. The fund will be used to support members who may be on strike against sick clubs, and, moreover, to pay for advertisements in the medical and non-medical press warning medical men against settling in a place where a strike is in progress. Young men will be advised against the study of medicine by regular communications sent by the union to the press. Apart from the central committee in Leipsic local committees will be formed throughout the country. The system is, in fact, the same as that adopted with great success by the trade-unions, but it is very doubtful whether the organisation of the medical profession is equal to the task of arranging strikes and preventing the clubs from appointing other medical men to fill the vacancies. The appeal of the committee has been received rather coldly by the medical profession, especially in Berlin. The Berlin medical journals doubt whether the strike fund will amount to a sufficient sum and say that other measures have, as far as Berlin is concerned, given better results They recommend the free-choice system, to which allusion has already been made in the columns of THE LANCET, and they blame the committee for having omitted to mention this system. In a recent communication from the committee the idea of a strike seems in fact to have been placed in the background; the free-choice system is favoured, and the aim of the union is described in more general terms. It is very unlikely that the movement will have any important result and the matter will probably be dropped after a time, like so many other schemes proposed for the benefit of the medical profession.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Eliminative and Antiseptic Treatment of Typhoid Fever.

IN my letter in THE LANCET of Oct. 13th (p. 1106) appeared a short item relative to the plan of treatment adopted by Dr. W. B Thistle of Toronto in typhoid fever of which, in justice to Dr. Thistle, correction should be made in that he does not claim to get rid of bacilli from the intestinal walls. Dr. Thistle has now been employing this plan of treatment for seven years and during that time he has never had a fatal hæmorrhage, any hæmorrhages that occurred having been always very slight, and he has never had any perforations.

Diphtheria in Toronto.

At the present time there is more diphtheria in Toronto than in any of the towns and cities of the province of Ontario, the record for the present year being:—January, 66 cases; February, 60; March, 57; April, 78; May, 50; June, 74; July, 67; August, 74; September, 83; total, 609 cases. Since 1887, when 618 cases were reported, the following has been the number of cases reported to the Health Department:—1888, 498; 1889 320; 1890, 433; 1891, 1039; 1892, 1625; 1893, 693; 1894 338; 1895, 506; 1896, 562; 1897, 719; 1898, 426; and 1899, 500. The season has been an exceptionally fine and dry one in Toronto, and Dr. Sheard, the medical health officer, considers that this factor has something to do with the increase this year. In the northern central districts, where the disease is most prevalent, many complaints have been made of the condition of the sewers, sewer-air being plentiful, and this is also deemed to be a contributing cause. Although a recommendation was passed by the Committee on Works this past spring that ventilators should be placed in the sewers to carry the gas up through them, nothing has been done in that direction and as a consequence the health of the community suffers.

Queen's University, Kingston.

Dr. Fife Fowler, who has been for over 50 years connected with the Medical Department of Queen's University, has resigned the professorship of the theory and practice of medicine, but will retain the honorary position of Dean of Faculty. Dr. James Third (Trinity, 1892), late superintendent of the Kingston General Hospital, succeeds Dr. Fowler, while Dr. Haig of Campbellford, Ontario, assumes control of the General Hospital. A by-law was recently submitted to the citizens of Kingston for municipal aid to the extent of $50 000 to Queen's University, which passed by a very large majority. Queen's is said to be ambitious to be raised to the status of provincial university for the eastern portion of the province of Ontario, and at the next session of the Legislature it will ask the Parliament of Ontario for financial recognition, believing that its capacity can now readily be raised from 500 to 1000 students. Toronto University, which is the provincial university, will oppose granting any aid to its eastern competitor, fearing that it would detract from its own importance and influence in educational matters in the province.

The Morrice Pharmacological Laboratory at McGill University.

Dr. J. T. Halsey, a graduate of Columbia College, New York, has been requested by the Faculty of Medicine of McGill University to take charge of the Morrice Pharmacological Laboratory, which is designed for the purpose of carrying on original research work in that department, and he has accepted the appointment. This laboratory has been equipped by a Mr. Morrice of Montreal, who promises also for the next five years to contribute an annual donation to enable the university to conduct this important work. Dr. Halsey, after graduation, was for one year *interne* at St. Luke's Hospital, New York. He then proceeded to Germany, where he has been for the past five years pursuing studies in the chemical, physiological, and pharmacological laboratories of Freiburg, Strasburg, and Marburg. In October, 1898, he was appointed assistant to Professor Hans Meyer in the University of Marburg, a position which he resigned to accept the offer from McGill University.

Toronto Clinical Society.

At the first regular meeting of this society for the season of 1900–1901, on the evening of Oct. 3rd, Dr. W. H. B. Aikins, the newly-elected president, occupied the chair and delivered the annual address, referring in complimentary terms to the honour which had recently been conferred on one of their number, Mr. I. H. Cameron, by the Royal College of Surgeons of England, and also to the work of Dr. Ryerson as Canadian Red Cross Commissioner to South Africa. Dr. Ryerson delivered a very interesting and able address on the Medical Side of the South African War, dealing principally with typhoid fever and inoculation for it, dysentery, veldt fever, &c. He considered it to be an important fact that in an army of 200,000 men there had not been a single case of small-pox. He eulogised the work of the hospital orderlies whom he thought ought to be commended very highly for their very trying and laborious yet noble work. Dr. G. Silverthorn showed a child of a little more than a year old who in July last had a retro-pharyngeal abscess following upon an attack of measles upon whom he operated through the sterno-mastoid muscle with such signal success that the child was able to leave the hospital completely recovered within one week. Professor H. B. Anderson of Trinity Medical College showed a patient, a young man, aged 23 years, who for 10 years had been the subject of frequent asthmatic attacks and who had had three attacks of right-sided pleurisy. He was shown as having his liver displaced as low as the umbilicus. The interesting point in this case of hepatoptosis is that it was associated with definite asthmatic attacks. Dr. Silverthorn also exhibited specimens showing the course of a bullet-wound in a man who had been shot. The wound of entrance was on the left breast, one and five-eighths inches outside of the nipple line and on a line with the nipple itself. On following this wound backward the bullet was found to have punctured the fifth rib, fracturing it and tearing up a portion of its upper edge, two and three-quarter inches from its junction with its cartilage. It then passed through the pleura and through the anterior angle of the upper lobe of the lung, and then through the pericardium; then along the left border of the heart, which it grooved up and passed on backwards, tunnelling the fat in the auriculo-ventricular groove; then passing out again from the pericardium, backwards through the anterior portion of the lower lobe of the lung, and still backwards into the aorta opposite the ninth dorsal vertebra, with a large amount of hæmorrhage in the posterior mediastinum. The bullet, however, could not be found in any place in that region. An examination of the arteries was then made and the missile was found in the left femoral artery just below where the profunda femoris is given off. The bullet was a quarter of an inch in diameter. In impinging the posterior wall of the aorta it had perforated that wall, supported behind by the vertebral column, had fallen into the artery and had been carried to its ultimate destination. The specimen of the artery was shown with the bullet *in situ*.

Legislation to Regulate the Sale of Patent or Proprietary Medicines or Cures in the Province of Ontario.

At the last session of the Legislature of the Province of Ontario Mr. W. M. German, one of its members, introduced a measure which at the present time is exciting considerable adverse comment and opposition amongst the drug fraternity of the province. The preamble of the Bill states that it is expedient in the public interest to legislate against the fraudulent or improper advertisement of drugs, medicines, or cures, and against the sale of such of the same as contain harmful ingredients, to license the advertisement or sale of patent or proprietary medicines, to appoint an inspector of the same, and to provide for the payment of licences in respect of the same. Article II. of this proposed measure will provide for the appointment of a "registrar" of proprietary medicines who shall be attached to the office of the Provincial Secretary of Ontario, and who shall be a member of the Ontario College of Pharmacy, regularly qualified, and of at least seven years' standing. The duties of this officer are set forth in detail in Article III., and without being explicit the entire control of the drug trade in this direction would be under his authority. Article V. provides that every application for a licence shall be accompanied by a statement of the formula or prescription of the medicine which shall be duly verified by affidavit. Licences shall cost $1000 and must be renewed yearly. An important section is Article XI. which provides that no person shall advertise any medicine in respect of which a licence has been granted by any surgical picture which would suggest the means of committing any crime, or by any advertisement which is offensive in its language or holds out false hopes of alleviation or cure, or which is misleading in its statement of the curative properties of the drug. An appeal from any decision of the registrar shall be taken to a judge of the High Court of Justice of Ontario within six months from the date of such decision. The measure further provides for fines and penalties. As a most profitable part of the business of a druggist in the province of Ontario consists in the sale of patent medicines and also in the manufacture and sale of preparations of his own, it can readily be seen how the proposed law will bear upon each and every druggist in the province who would be required, under the provisions of this Act, if it became law, to recoup the province to the extent of $1000 for a licence and a similar sum for its renewal annually, and if he wished to sell 10 different formulæ he would be required to pay into the treasury $10,000. It has been interesting to watch the action of the various newspapers throughout the province who profit largely by advertisements of these patent cure-alls. They are standing hand-in-hand with the proprietors of "trade-mark" articles with the object of defeating the Bill, for the framing and pushing of which the Medical Council is charged with the responsibility. The "German Bill" as it is called, is without doubt a good one in certain particulars. It has been endorsed by a leading society paper, which gives the newspapers some pretty hard raps on the character of the advertisements which they are continually inserting, pointing out that some of those self-same newspapers which are foremost in opposition are also first as respects the publication of the offensive advertisements. The patent medicine trade needs regulating in this province, certainly as well as objectionable advertisements, and the suggestion of the *Dominion Medical Monthly* in a recent issue that the time was opportune for the appointment of a medical editor on the staff of the leading dailies to look after medical items which are popular in the press nowadays, as well as to exert an influence in shutting out these disgraceful advertisements, would, if acted on, result in a cleaner lay press in this particular direction.

Toronto, Oct. 22nd.

DEATH FROM ICE-CREAM.—The borough coroner of Plymouth held an inquest on Nov. 1st upon the body of a boy, aged 12 years, who had partaken of four or five ice-creams on Oct. 27th and died on Oct. 30th. A medical witness who had made a post-mortem examination stated that death was due to ptomaine poisoning the result of eating the ice-creams, and the jury returned a verdict to that effect.

Medical News.

The National Registration of Plumbers: Conference at Birmingham.—The Lord Mayor of Birmingham presided at a public meeting held in the Council Chamber, Birmingham, on Oct. 24th, among those present being Mr. Robert Crawford of Glasgow and Alderman Richard Hind, representing the Worshipful Company of Plumbers; Dr. Alfred Hill, medical officer of health of Birmingham; Alderman Cook, chairman of the Birmingham Health Committee; Alderman Parker, chairman of the Birmingham Water Committee; Mr. John Price, city surveyor, Birmingham; Vice-Principal Heath, of the Birmingham University; Bailie Dick, chairman of the Health Committee, Glasgow; Mr. G. H. Fosbroke, medical officer of health of Worcestershire; Dr. A. Bostock Hill, medical officer of health of Warwickshire; Dr. P. Boobbyer, medical officer of health of Nottingham; Mr. F. M. Williams, medical officer of health of Plymouth; Professor Matthew Hay, Aberdeen; Dr. W. A. Evans, medical officer of health of Bradford; and several master plumbers and operative plumbers representing various associations and the district councils working in conjunction with the National Registration of Plumbers. Previously to the public meeting a conference was held in the Council Chamber under the presidency of Mr. Robert Crawford, at which the following resolutions were passed. It was proposed by the Chairman and seconded by Dr. Alfred Hill:—

> That in the opinion of this Conference, representing the public health and water authorities and the master and operative plumbers of Great Britain and Ireland, it is desirable, and would be a great public advantage, if a measure should be passed through Parliament with the object of protecting the public from the results of bad and incompetent workmanship and securing the efficiency and responsibility of plumbers through a system of registration of the qualified masters and operatives; and that it is the duty of the Government, acting in the public interest, to carry through a measure with this object.

It was proposed by Mr. F. M. Williams and seconded by Bailie Dick:—

> That 12 representatives of the district councils be appointed to act in conjunction with the company in approaching the Local Government Board for the purpose of framing a scheme for a Plumbers' Registration Bill, and taking such steps as they may deem necessary for such legislation.

It was proposed by Professor Matthew Hay and seconded by Dr. Bostock Hill:—

> That this Conference approves of the establishment of two grades of registration, one for operative plumbers, in which the examinations would be essentially a test of workmanship and an oral examination substituted for the present written examination, and the other requiring a higher standard of technical knowledge for master plumbers, inspectors, and plumbers occupying similar positions; and that it be remitted to the company and the representatives of the Conference already appointed to prepare a scheme under this resolution, including the question of fees, and after submitting it to the district councils for their opinion, and finally adjusting it, to put the scheme into operation.

The Lord Mayor in welcoming the members of the conference said he was glad to think that it was many years since Birmingham began to show its interest in matters affecting the public health. When the water-pipes leaked people were anxious about their ceilings and carpets and lost no time in sending for the plumber, but when there was a bad smell they were not so eager to do so. The plumber was not always a popular person, and those who watched him at work were apt to think that his methods were somewhat deliberate. He was a man they could not do without, although he was perhaps the most abused artisan in all the sections of the building trade. The public, it was to be feared, did not appreciate sufficiently the necessity of looking after all those invisible matters which only make themselves known by their odour. Surely, then, it was all the more important to large communities like theirs that the trade on which all that depended should be of the best possible character. It was for that reason that he was there with his colleagues on the Health Committee. Why should it be difficult to get through an Act of Parliament the necessity for which he thought nobody would deny? They could not get it through because it was not a Government matter, and it must be apparent to everyone who had any experience of Parliamentary procedure that by continual working it must be made clear that it was a matter for Government interference. He believed that they had got hold of the right principle and that in time the principle would be recognised in the way they desired.—Mr. Robert Crawford, as chairman of the conference, read the resolutions passed at the conference. He said the plumbers of this country and their public representatives had been engaged during the past 16 years in educating the public, the local authorities, and the masters and men in the trade, and in creating a higher standard of appreciation of knowledge and of responsibility. At the present moment the British plumber stood at the head of his profession in the world. Those who travelled abroad must see that the old insanitary and slipshod methods of the continent were being forced aside. Throughout Europe, in all the most important hotels and institutions and good private houses, the British plumber had been recognised; he had taken possession of the continent from the plumbing point of view, just as his fellow-countrymen had taken possession of most of the unoccupied parts of the earth in other capacities.—Alderman Cook brought forward a motion endorsing the decisions of the conference, warmly supporting its efforts in the interests of the public health, and urging the Government to carry through the Bill for the National Registration of Plumbers.

Royal College of Surgeons in Ireland: Examination for Registered Practitioners.—Mr. William Robert Wilson, L.S.A. Lond., having passed the necessary examination, has been admitted a Licentiate in Surgery of the College.

The Dental Hospital of London, Leicester-square, has received a donation of £100 and a new yearly subscription of £10 10*s.* to the "general maintenance" fund and £100 as a special donation towards the amount urgently required for re-building the hospital, from Lord Grimthorpe, Q.C.

Shooting a Medical Man.—Sidney James Kirby, dairyman, was charged on remand at Leicester on Tuesday last with the attempted murder of Dr. Clarke by shooting him with a revolver at Leicester on Oct. 8th. Dr. Clarke, who had recovered sufficiently to give evidence, stated that in 1896 he certified the accused as insane. The accused, who behaved in an excited manner and did not seem to realise his position, was committed for trial.

Memorial to Dr. Augustin Prichard.—On Nov. 1st, at Redland Green Chapel, a window was dedicated to the memory of the late Dr. Augustin Prichard of Clifton. The window contains the figures of St. Luke and St. Barnabas and has a suitable inscription. There was a large attendance at the service among those present being several leading citizens who had held Dr. Prichard in high esteem.

University College of South Wales and Monmouthshire.—On Oct. 31st Principal Viriamu Jones, with a deputation from the University College of South Wales, attended the meeting of the Cardiff Town Council and made an earnest appeal for the granting of a free site in Cathays Park for the proposed new college buildings. The college, he stated, had only £50,000 out of the £150,000 which were required, and there was no possibility of obtaining sufficient funds to purchase the site for the sum required by the corporation. After some discussion it was eventually decided that the recommendation of the committee that the college should purchase the site should be referred back for reconsideration.

Kent County Ophthalmic Hospital, Maidstone: Resignation of Mr. M. A. Adams, F.R.C.S. Eng.—At a meeting of the board of management of this institution held in September last the resignation of Mr. Adams was received and with great regret accepted. A resolution was passed expressing on behalf of the governors and subscribers their deep sense of indebtedness to Mr. Adams and their appreciation of the assiduous and gratuitous services rendered to them and to the inhabitants of the county of Kent for the long period of more than 37 years, during which time he had been the surgeon to the hospital and upon whom had devolved to so large an extent the conduct of the institution, and to whom are largely due the benefits conferred upon the many thousands who had availed themselves of that free institution. At the following meeting of the board Mr. Ernest H. Cartwright, B.Ch., M.D. Oxon., was appointed surgeon in succession to Mr. Adams. Dr. Cartwright has up to this time acted as assistant honorary surgeon to the hospital.

GLASGOW OPHTHALMIC INSTITUTION · POST-GRADUATE COURSE OF DEMONSTRATIONS ON DISEASES AND INJURIES OF THE EYE—This course was commenced on Tuesday evening, Nov. 6th, over 50 graduates being present Dr. A M Ramsay took as his subject "Phlyctenular Conjunctivitis" and at the close of the lecture Dr. M Thomas, medical superintendent of the Glasgow Royal Infirmary, on behalf of the managers, welcomed the members of the profession and expressed his gratification at the increasing interest manifested in these annual demonstrations

MEDICAL MAGISTRATE—Mr. T. W. Buckley, M.D. Durh., of Thrapston, has been placed on the commission of the peace for the county of Northamptonshire, on the recommendation of the Lord Lieutenant, Earl Spencer, K.G

SOUTH AFRICAN HOSPITALS COMMISSION.

Evidence of Mrs Richard Chamberlain

THE Royal Commission appointed to inquire into and report upon the care and treatment of the sick and wounded in the South African campaign held its final meeting for the examination of witnesses on Monday, Nov. 5th, in one of the rooms of Burlington House The Commissioners present were Lord Justice Romer, Chairman, Dr W. S Church, and Sir David Richmond, and the witness examined was Mrs Richard Chamberlain

Mrs CHAMBERLAIN said, in reply to the CHAIRMAN, that she landed at Cape Town about the beginning of November and left on August 8th During nearly the whole of the intervening period she was in the vicinity of Cape Town, though she paid a visit to Mafeking and saw the hospital there run half upon the military and half upon the civil system The hospital to which she paid most attention was the No 1 Wynberg Hospital She also paid attention to No 2 Wynberg Hospital, she twice visited the Woodstock Hospital, and she was shown over No 3 Hospital But she only considered herself an authority with regard to No. 1 Wynberg Hospital She obtained permission from General Walker to visit this hospital General Walker told her that he had arranged for her to visit it, but when she went she was politely shown the way out. When she reported this treatment to General Walker he said there must have been a mistake, and matters having been arranged, she began to visit the hospital regularly. She got permission to visit three days a week, but as a matter of fact she was there every day No complaint was made at the time by the principal medical officer, but seven months later after she had reported him, there was complaint. General Walker made no representation to her about the matter, and when the General commanding the line of communications remarked that although the permission was for three days a week she was going to the hospital every day, he added that he supposed they were always glad to see her No difficulty arose between her and the principal medical officer until some time after Christmas, and the difficulties arose because she had reported him several times to the General, to the Base Commandant, to Colonel Stevenson, and in fact to anybody of authority she could get hold of The principal medical officer never complained that she gave things to the patients without his knowledge, but she heard indirectly from somebody else, a woman, that it was said she had given buns to enteric fever patients and that she had taken an ice-bag from the head of one patient. These statements were absolutely untrue She was absolutely sure that she had never given things to the patients without the knowledge of the principal medical officer. When at the request of the principal medical officer she gave a Christmas party to all the patients she forbade the ladies assisting her to hand food to the patients, she said that the orderlies who were in charge of the patients must be the ones to judge what the patients were to have As far as her own handing of food was concerned she not only looked at the diet sheet before giving anything, even tea, but in addition she used to ask the sister or the orderly One day somebody sent up to her to say that the Government stores of tobacco had run out and to ask for some of her tobacco They asked if they could borrow from her She replied that it was unnecessary to borrow for she would give the men some of her tobacco on the following day, she told the medical officer that she preferred to distribute her tobacco herself She admitted writing a letter containing this passage: "Surgeon General be blowed, I am going to give the men cigarettes to-morrow myself The hospital authorities said she was not to go to the hospital, but all the same she continued to go She said she would not go inside the hospital unless she was sent for specially by some patient who wanted to see her She paid three visits after being told not to enter the hospital They sent a sergeant to her, and she told him to go back to his superiors and say to them that he had communicated to her their orders As a matter of fact she disregarded their orders and went three times to the hospital—each time in response to a written message from a patient.

The CHAIRMAN In other words, for reasons of your own, you disobeyed the orders and consequently had to be excluded by an order of Lord Roberts?

Mrs CHAMBERLAIN: Yes, but surely the reasons are important.

The CHAIRMAN Now we will go to your personal experiences of the Wynberg Hospital

Mrs CHAMBERLAIN said that in the first instance it seemed to her that the whole place was in a most terrible muddle. There was no organisation, and though they had unlimited money and stores at their command the place did not look like a hospital. There was an absence of proper method in regard to the convoys coming to the hospital. The authorities of the hospital ought to have sent down to the station a medical officer of high rank to sort out and to classify the patients so that on their arrival at the hospital they could be put into the proper beds.

Dr CHURCH They were sorted when they got to the hospital

Mrs CHAMBERLAIN Very imperfectly

The CHAIRMAN You appear to think that you know better than the doctors?

Mrs CHAMBERLAIN Yes, I think I know much better than some of these doctors In reply to further questions by the CHAIRMAN, witness said that they were always short of splints in the hospital. She knew that because she saw people contriving makeshift splints and heard them saying these were all they could get They were short of every necessary utensil from cups and saucers and plates down to bed pans and things of that sort. This shortness prevailed all the time There were no proper air cushions or air beds or hot-water bottles or pillows, only the tiny regulation pillow They were, indeed, short of everything except drugs They had a very insufficient supply of nursing sisters When she first went to the hospital, she and a civil surgeon made a calculation and they found that there was one nursing sister to every 175 patients, counting night and day She could not tell the total number of patients or of nursing sisters, though she had the figures in her notes, but she assured the Commissioners that the proportion she had stated was correct There were plenty of nurses to be had, it was simply a question of red tape She considered that after the first rush there were enough orderlies if they had been properly organised and been taught a little about their work She could have arranged matters differently She herself provided soups and jellies and air-cushions and pillows

The CHAIRMAN They accepted your gifts?

Mrs CHAMBERLAIN Yes

The CHAIRMAN Did you complain of them for that?

Mrs CHAMBERLAIN No, but I complained of the things not being there She further said that they were even short of soap There was nothing in the way of chairs or couches on which to put patients and nothing in the way of warm things with which to wrap up patients after sundown when the temperature became very cold They were short of feeders and tubs and new linen, and utensils for hot water for *fomentations Indeed, it was difficult to keep some of the patients* reasonably clean She had further to complain of the dirt in the place All the time until the news came of this Royal Commission, the place was swarming with vermin, the floors were dirty, everything smelt a bit, the utensils were not disinfected, and the patients were not properly washed The buildings were occasionally washed down with dirty water She did not consider that the walls were dirty, though of course, the bugs came out of the crevices The system of night nursing for the orderlies was very bad The men were posted in batches and put in a tent and each man was supposed to be on duty for two hours There ought to have been proper night orderlies who were not called upon during the day In the officers' mess she observed great waste and the absence of proper supervision She saw napkins used for cleaning knives, crockery knocked about and smashed, and two-thirds of the wine and spirits dealt out for the mess were stolen The food was improperly cooked and dirtily served Although the officers had their servants with them they were supposed to be looked after by the orderlies, the servants' duties not being properly defined She did not make the allegation of theft against the officers' servants; she said that more probably the wine and spirits were stolen by the orderlies Another complaint she had to make was that while there was any amount of fresh milk to be had around the hospital the patients were very often without it and had to be content with tinned milk She had seen both officers and men who could not have fresh milk Another thing she objected to very strongly was that although there were typhoid and other diseases prevalent in the neighbourhood of Wynberg the milk was not sterilised, and her fear always was that diphtheria or scarlet fever might be communicated by the milk She called attention to the need of sterilisation several times, but later on gave up the business as hopeless. She had seen orderlies take sheets that had been used on the beds of typhoid patients, rinse them through with cold water, dry them, and then place them on beds for new patients. She had no doubt on the point for she had witnessed the whole process Men who had never been to the front contracted typhoid and this she attributed to want of proper precautions in the hospital She complained that there was no proper inspection by the military authorities The doctors were practically allowed to do what they liked If the general came down he gave several days' notice and she did not consider an inspection was worth anything if notice of it were given In her opinion the inspection should be made without notice and by somebody outside the Army Medical Department. She objected to drunken army doctors being sent off in charge of convoys There was a doctor at No 2 Hospital whom she saw at intervals generally intoxicated for some months, and when he got into a row and was turned out of the hospital he was sent home in charge of transports There were other cases which she put before Lord Lansdowne and his lordship found them to be true There were two other doctors who were frequently drunk who were sent home in charge of invalids on transports.

The CHAIRMAN *invited* Mrs. Chamberlain to write down the names of the three doctors she referred to as well as the names of the transport ships on which they acted

Mrs CHAMBERLAIN, while writing in response to the CHAIRMAN, said that one of the doctors was a very nice young man and she would rather not give his name

The CHAIRMAN, having received the paper from Mrs Chamberlain, said there was only one doctor named

Mrs CHAMBERLAIN admitted she had only written one name but she had given the names of the three ships she could not keep all the names in her head

Dr CHURCH It is a serious charge you are making, that it is the practice to put drunken medical men on transports.

Mrs CHAMBERLAIN: Yes, it is the practice. When they want to get rid of the drunken medical men they put them on transports Another thing to which she desired to call attention was the manner in which complaints were received When complaints were made she considered that they ought to have been more looked into than they were

The CHAIRMAN reminded Mrs. Chamberlain that the Commissioners were now at the end and not at the beginning of their inquiry that they probably knew more about these matters than she did, and invited her to confine her evidence to matters of her own knowledge and experience

Mrs CHAMBERLAIN You remind me of a counsel for the defence. If I had not known who you were I should have thought you were the counsel retained by the army doctors

The Chairman: Quite an erroneous impression, I assure you, Mrs. Chamberlain.

Mrs. Chamberlain: Well, I think a witness should be assumed to be truthful until she is proved otherwise, and I think you should hear my evidence

The Chairman assured Mrs. Chamberlain that he had every desire to be courteous to her and that his only desire was to avoid mere expressions of opinion and to keep the evidence to matters of experience and fact.

Mrs. Chamberlain, in further examination, said that she had to complain of the manner in which lunatics were treated in the hospital. They had several lunatics and she maintained that they ought to have been put somewhere else and not allowed to go about the hospital and disturb and frighten the patients One was a young officer of the Royal Artillery who roved all over the place and used to dance into the wards where the most serious cases were, causing great fright and alarm and confusion. This went on for quite a considerable time until he became violent to an orderly and he was removed in an ambulance. She thought the man should have been put either in a small place by himself or in a proper lunatic asylum.

The Chairman: Do you not think the doctor was a better judge than you of what should be done with a lunatic patient?

Mrs. Chamberlain: I am sure he was not One case had a fatal termination. A young Army Service Corps officer came down suffering from a different form of insanity. He was very melancholy and when she spoke to him he said that he was miserable. Once before he had tried to poison himself. In her opinion they did not give him proper supervision in the hospital. They let him wander about, and out of pity she used to take him down to her hut and talk to him and give him something to think about. They took him down to the military sanatorium at Claremont They gave no warning to the authorities of the sanatorium and he shot himself next morning. All she could say about the Woodstock Hospital was that it was filthily dirty. She considered Wynberg bad, but Woodstock was worse, but that, of course, was before this Commission went out to South Africa. She went to Rondebosch once, and considering that it was a military hospital and run upon a bad system she thought it reflected great credit upon the officer in charge She was asked to go up to Mafeking by the chief magistrates of the place in order to see the hospital, one portion of which was run on the military and the other on the civil system. The sight was interesting because of the contrast it offered. When she went into the military portion she saw a man who appeared to be dying from enteric fever. She called the sergeant-major, who said, "We think we may just pull him through with great care." By the bedside there was some tinned milk very badly mixed indeed. The patient said he could not drink it, and the sergeant-major said he could not get fresh milk. She moved across to the civil portion of the hospital, where she saw convalescents with great bowls of fresh milk.

By Dr. Church: She had had considerable experience of hospital work in Birmingham and in the Guards Hospital in Rochester-row, but she had never trained in a hospital.

By Sir David Richmond: She did not pretend to be qualified to say whether a patient should or should not have tobacco. She always inquired of the orderly which of the men were allowed to smoke by the medical officer. She took care that her distribution did not take the place of theirs and did not clash with theirs

This closed the examination of Mrs. Chamberlain, and the Chairman announced that no more witnesses would be called, and that the Commissioners would now proceed to the consideration and preparation of their report.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Ainslie, William, M.B., Ch.B. Aberd., has been appointed Certifying Surgeon under the Factory Acts for the Kington Urban District and Kington Rural District, except the Civil Parishes of Eardisley, Willersley, Winforton, and Brilley.

Aymer C., M B, C. M. Aberd, has been appointed Certifying Surgeon under the Factory Acts for the Burgh of Inverbervie and the St. Cyrus District of Kincardineshire.

Bigger, E. C, M D. Irel, M Ch., L. M. R.C P., R C.P.S. Irel., has been appointed Local Government Inspector, Belfast.

Campbell, John Archibald, L.R.C.P. & S. Edin, L F.P S. Glasg., has been appointed Demonstrator of Anatomy at Anderson's College Medical School, Glasgow.

Durham, Frederic, M B., F.R.C.S, has been appointed Consulting Surgeon to the North-West London Hospital, Kentish Town-road, N.W.

Grant, Lachlan, M.D Edin., has been appointed Parish Medical Officer and Public Vaccinator, Ballachulish and Glencoe; also Certifying Factory Surgeon for the Parish of Lismore and Appin, Argyleshire.

Ham, B. Burnett, M D., M.R.C.S., L.R.C.P., D.P.H. Cantab., has been appointed Commissioner of Public Health for Queensland, Australia.

Lightbody, J. H., M D. Vict., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Urban District of Bexhill-on-Sea.

MacGuire F. J., L.R C.P., L R C.S. Irel., has been appointed Medical Officer for the Longford Workhouse, vice R. S. Cochrane, deceased.

Macquarie, J., M.B., C M. Aberd., has been appointed District Medical Officer, Wigton Union, vice T P. Thompson, resigned.

Maudsley, N., M.B., C.M. Edin., has been appointed District Medical Officer Rothbury Union, vice W F. Miller, resigned.

Moorhead, John, M.A., M.D., has been appointed Consulting Physician to the Royal Hospital, Weymouth.

Mudge, T., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Hayle District of Cornwall.

O'Meara, W. H., L R.C.P., L R.C.S. Edin., has been appointed Medical Officer for the Workhouse, Holbeach Union, vice R. R. Harper, resigned.

Pollock, R. G., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer for the Croydon Union, vice H. Ross-Todd, resigned.

Robb, A. G., M B. Irel., has been appointed Superintendent Medical Officer to the Fever Hospital, Belfast Union, vice E Cory Bigger.

Roberts, Adeline M., M.B. Lond., has been appointed House Surgeon to the Manchester Clinical Hospital for Women and Children, Park-place, Cheetham Hill-road, vice N. Lomas.

Sandstein, A. C, M.B., Ch.B. Edin, has been appointed Resident Medical Officer to the Gesto Hospital, Edinbane, Isle of Skye.

Thomas, Frank G., M.B., B.Ch. Cantab., has been appointed Ophthalmic Surgeon to the Swansea General Hospital.

Thomas, Jabez F.R.C.S. Eng., L R.C.P. Edin., L.S.A., has been appointed Consulting Surgeon to the Swansea General Hospital

Thomson, Sir William, M.D., M.Ch. Irel., F.R.C.S. Irel., has been appointed one of the Surgeons-in-Ordinary to the Queen in Ireland, vice Sir William Stokes, deceased.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead and Wirral Children's Hospital, Woodchurch-road, Birkenhead.—House Surgeon for twelve months. Salary £100 per annum, with board, residence, and laundry.

Birmingham and Midland Hospital for Skin and Urinary Diseases, John Bright-street, Birmingham.—Clinical Assistant

British Hospital, Oporto, Portugal.—Medical Officer. Salary £150 per annum, with liberty to engage in private practice. Apply to the Treasurer, Mr. R. Coverley, 55, Rua da Reboleira, Oporto.

Cardiff Infirmary.—Assistant House Surgeon for six months. Salary at the rate of £75 per annum, with board, washing, and apartments.

Central London Sick Asylums District.—First and Second Assistant Medical Officer and Dispenser at either of the Asylums at Cleveland-street or Hendon. Salary of the First Assistant Medical Officer £100 per annum, and of the Second £75 per annum, each, with board and residence, for twelve months. Subject to statutory deductions, Apply to the Clerk, Clerk's Office, Cleveland street Asylum Cleveland-street, London, W.

Coomassie Expedition.—Medical Officers for six months in the colony, with a salary at the rate of £30 a month, and a gratuity on returning to England of ten days' pay in respect of each complete calendar month served in the colony. Free passage to and from the colony and free rations will be provided. Applications to be addressed to the Assistant Private Secretary, Colonial Office, London.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150 by £10 annually, with board, furnished apartments, &c.

Grimsby and District Hospital Great Grimsby.—Resident House Surgeon. Salary £80 per annum board, lodging, and washing.

Hailey Open-air Sanatorium, Wallingford.—Resident Assistant Physician. Salary £100.

Hartlepools Hospital.—House Surgeon. Salary £80 per annum, with board, and lodging in the institution.

Holloway and North Islington Dispensary, Palmer-place, N.—Honorary Medical Officer.

Holloway Sanatorium Hospital for the Insane, Virginia Water, Surrey.—Junior Assistant Medical Officer for the male side. Salary £150 per annum, rising to £200, with board, lodging, washing, and attendance.

Hospital for Sick Children, Great Ormond-street, London.—Resident Medical Superintendent for one year. Salary 100 guineas, with board and residence in the Hospital. Also Ophthalmic Surgeon.

Kent and Canterbury Hospital.—Assistant House Surgeon, unmarried. Salary £60 a year, with board and lodging.

Kent County Asylum, Chartham, near Canterbury.—Second Assistant Medical Officer, unmarried. Salary begins at £175 per annum, with board, quarters, washing and attendance. Also Third Assistant Medical Officer required in January next. Salary begins at £125, with emoluments as above.

Liverpool Dispensaries Moorfields, Liverpool.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer for the In-patient Department, Bowdon, Cheshire. Salary £100 per annum, with board, apartments, and washing.

Manchester Royal Infirmary.—Resident Medical Officer for the Convalescent Hospital at Cheadle, for twelve months, unmarried. Salary £150, with board and residence.

Metropolitan Asylums Board.—Four Assistant Medical Officers at the Fever and Small-pox Hospitals (no vacancy for a Female Medical Officer), unmarried. Salary £160 per annum the first year, £180 the second year, and £200 the third and subsequent years, with board, lodging, attendance, and washing (subject to statutory deduction).—Apply at the Office of the Board, Thames Embankment E C.

National Orthopædic Hospital, 234, Great Portland-street, Regent's Park, London.—Surgical Registrar.

New Hospital for Women, 144, Euston-road, London.—Two fully qualified medical women as House Physician and House Surgeon. Also Clinical Assistant for Out-patient Department for one year.

North-Eastern Hospital for Children, Hackney-road, London.—House Surgeon for six months. Salary at the rate of £80 per annum, with board, residence, and laundry allowances. Apply to the Secretary, City Office, 27, Clement's-lane, Lombard-street, E.C.

NORTH WEST LONDON HOSPITAL, Kentish Town road —Assistant Surgeon Also Resident Medical Officer and Assistant Resident Medical Officer for six months Salary at the rate of £50 per annum, with board, residence, and wahing

NOTTINGHAM CITY ASYLUM —Senior Assistant Medical Officer, unmarried Salary £200 a year, with board, apartments, and washing

PARISH OF ST. PANCRAS, London —Senior Assistant Medical Officer for the Workhouse, for two years Salary £135 per annum, with residential allowances. Apply to the Clerk to the Guardians, Vestry Hall, Pancras road, S W

PECKHAM HOUSE ASYLUM, S E —Junior Assistant Medical Officer, unmarried Salary £150 per annum, with board, residence, &c

ROYAL ACADEMY OF ARTS, London — Professorship of Anatomy. Tenable for five years The annual fee for six lectures and six demonstrations to the students, is for the lectures £100, and for the demonstrations £28 Apply to the Secretary, Royal Academy of Arts, W

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months Salary at the rate of £40 per annum, with board, lodging, and washing

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road, Brighton —Acting Physician

ROYAL DEVON AND EXETER HOSPITAL, Exeter —Assistant House Surgeon for six months Salary at the rate of £80 per annum, with board lodging, and washing

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W C —Clinical Assistants for six months

SALISBURY INFIRMARY —House Physician, unmarried. Salary £75 per annum, with board, lodging, and washing

SUSSEX COUNTY HOSPITAL, Brighton —Resident Pathologist. Salary £70 per annum, with board and residence

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies as Certifying Surgeons under the Factory Acts at Tisbury, in the county of Wilts, at Haverfordwest, in the county of Pembroke, and at Wishaw, in the county of Lanark.

VICTORIA HOSPITAL FOR CHILDREN, Queen's road, Chelsea, S.W.—House Physician for six months Honorarium £25, with board and lodging in the Hospital

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance

Births, Marriages, and Deaths.

BIRTHS.

ALLAN —On Nov. 4th, the wife of Alex. W. Allan, M D, Wainfleet, Lincolnshire, of a son

CULMER —On Oct 31st, at Chinehurst, Alum Chine-road, Bournemouth, the wife of J. W. Culmer, M.R C S, L R C P, of a son

KEATS —On Oct. 26th, the wife of William J C Keats, Medical Superintendent of Camberwell Infirmary, of a daughter

KINGDON ELLIS —On Oct 30th, at Lowdham Notts, the wife of Robert Kingdon-Ellis, M.A, M B Oxon, of a daughter.

WALTERS —On Nov. 3rd, the wife of Dr. F Rufenacht Walters, of 21, Wimpole-street and Crooksbury Ridges, Farnham, of a daughter

MARRIAGES.

CHURCHILL—HUBERT.—On the 31st Oct., at St. Mary's, Billingshurst, Sussex, by the Rev A H Barrow, vicar, assisted by the Rev S Norman and the Rev G H Torrance, John Aylward, M R.C S, L.R.C P, only son of John Foot Churchill, M R.C S, L.R.C P, of Chesham, Bucks, to Sybil Maude, only daughter of William Henry Hubert, M R C S, L.S A, of the Brick House, Billingshurst

CRIMMIN—LENNAN —Oct 29th, at the Church of St. Joseph, Terenure, by the Very Rev Terence Anderson P P Major John Crimmin, V C, Indian Medical Service, to Julia (Juju), only daughter of William F. Lennan and Mrs Lennan, St. Ronan's, Orwell road, Rathgar, co Dublin, and granddaughter of the late Major J. J. Poett, Indian Army. No cards

MARRIOTT—GOCHER On the 8th inst. at the parish church, Edgbaston, by the Rev Horatio Spurrier, M A., vicar of Shildon (uncle of the bridegroom), assisted by the Rev Canon Cresswell Strange, M A, vicar of the parish, Hyde Marriott, B Sc. M B Lond, eldest son of the late Joshua Marriott of Stockport, to Emily Katharine, third daughter of Thomas Gocher, of Edgbaston At home Dec 5th, 6th, and 7th No cards

SWALLOW—ATKINSON —On Nov 1st, at All Saints' Church, South Lambeth, S W, Allan James Swallow, M B, B S, of Mount Ringcombe-gardens Clapham rise, S W., to Elizabeth, elder daughter of the late John Bewley Atkinson, of Chertsey hill, Harraby, Carlisle.

DEATHS

ANDREWS —On Nov. 4th, at Curzon House, Ridgway, Wimbledon, Frederic Foster Andrews, M D, aged 73 (formerly of) 29, Eccleston-street, S.W

BARRY On Nov 5th, at Westbourne Park-road, Bayswater, Richard John Barry, Fleet Surgeon, R N, aged 54

HALE —On Nov 4th, at Barrow Hill, Chesterfield, Thomas Frederick Hale, M R.C S, aged 74 years No cards.

HUGHES —On Nov. 3rd, at Chester-terrace Regent's Park, London, Alfred William Hughes, F R.C S, Professor of Anatomy at King's College London, aged 38.

MORLEY —On Nov 2nd, at Hartington street, Derby, Henry Morley, L D S Eng aged 73 years

SHORTO —On Nov 2nd, at 5, Trinity road Wimbledon, James Reeve Shorto, M R C S, L S A, aged 64 formerly of Southampton.

N.B —A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

A MEMORIAL TO THE GENERAL MEDICAL COUNCIL FROM THE MIDDLESBROUGH AND DISTRICT MEDICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—Knowing what an interest you take in all forms of medical organisation I should be glad if you will grant me a little space to let you know some of the work that has been done and is being done in this district. Since the formation of our medical society there has been a steady increase in its membership, which now includes every medical practitioner in the town and district with one exception Much good work has been done in reforming old bad habits amongst us and in raising the standard of medical practice generally Amongst these reforms (one of the most needed in an industrial town like this) was an unanimous resolution prohibiting members (1) employing collectors to canvass for members for private family clubs, or (2) associating themselves with "canvassing" in any form This naturally involved the medical men holding appointments under the various medical aid societies in the town and in view of, the strong disapproval of the General Medical Council at medical practitioners associating themselves with societies who systematically canvass for members (see resolution, June, 1899), it was unanimously resolved that no member of our society should hold any post under any medical aid society and that all present appointments should be given up This resolution has been acted upon, with the result that the medical aid societies advertised for and procured the services of a qualified medical man. On the arrival of Dr X in the town he was waited on by a deputation from our medical society and in a most friendly way was asked to reconsider his action in supporting the medical aid societies here when all the local medical men had expressed their disapproval of those societies. As Dr X still persisted in his action it was resolved to memorialise the General Medical Council, calling their attention to what, in the opinion of the Middlesbrough and District Medical Society, was a case falling within the terms of their resolution of June 1899 This memorial has now been drawn up and signed by all medical men practising in the town and district and forwarded to the General Medical Council At the Manchester conference strong disapproval was expressed as to the way in which medical aid societies exploited the services of general practitioners in order to secure members The ruling of the General Medical Council on this matter was discussed, and it was asked if their disapproval was anything more than a "pious opinion" We were told that no specific case had been brought to the notice of the Council since the resolution bearing on medical aid societies was passed It is with the object of placing a "specific case" before the General Medical Council that our society has taken this action, trusting that it may be the means of obtaining some decision from the Council which will prohibit general practitioners from associating themselves with this very objectionable form of contract work.—I am, Sirs, yours faithfully,

R E HOWELL, M B Edin., M R.C.S Eng,
Honorary Secretary Middlesbrough and District
Medical Society

Nov 6th, 1900.

⁂ The Middlesbrough and District Medical Society has given to the General Medical Council a test case The result will be watched by the medical profession with interest.—ED L.

THE CASE OF MR. JOSEPH HENDERSON MARTIN

To the Editors of THE LANCET.

SIRS,—A fortnight ago Mr Joseph Henderson Martin, M.R.C S. Eng, L.S A., whilst acting as assistant in charge of a branch colliery practice at Lumley, co Durham, became insane and through lack of means had to be removed to the County Asylum at Sedgefield His wife and five young children (ages, 12, 10, nine six, and four years) are practically destitute, and I venture to appeal on their behalf through your influential columns

Mr Martin was a student at the Middlesex Hospital, has filled several assistantships—one at Richmond in Yorkshire, one in Leicester—and for a time he practised on his own account in Huntingdon. He is only 43 years of age, and through no absolute fault of his own has never been in a position to lay by any money I understand that during the last two years of his life he has been freer from money troubles than he had ever been before, and his income then would be about £200 and a house Any subscriptions in aid of this unfortunate family would be thankfully received by Dr W M Renton, St. Mary's House, Chester-le-street, or by yours faithfully,

H LYON SMITH.

The Hawthorns, Chester le Street, Nov 7th, 1900

THE "MEDICO" TEA INFUSER.

THIS teapot is very ingeniously as well as simply designed in order to place the infusion of tea leaves under easy control. The space beneath the lid which contains a perforated cup or strainer is occupied by what may be described as a wide dip tube. The tea leaves are placed in the strainer and hot water is poured in until the level of the water is just above the strainer and the leaves are immersed. There is an annular space around the strainer just beneath the shoulder of the teapot. On pouring in hot water the water traps air in this space after the manner of a seal. Thus the level of the water in the strainer is higher than that in the teapot owing to the imprisoned air. So long as this is so the process of infusion proceeds, but it may be immediately stopped by unscrewing a little air-valve on the shoulder of the teapot. The trapped air then escapes and the water in the strainer sinks and that in the teapot rises until a common level is obtained. At this point, of course, the leaves are left "high and dry" and out of contact with the water. In this way the infusion of the tea may be easily controlled. The device is to be commended since it admits of tea being made correctly with a minimum of trouble; there is no extreme extraction of the pernicious astringent substances of tea-leaves, a delicate wholesome liquor being obtained which may stand for some time without taking up an objectionable excess of tannin. The difference between tea thus made and the tea made in the ordinary teapot and allowed to stand is the difference between tea that is fit to drink, as in the former case, and unfit to drink, as in the latter case. Mr. John Marshall of 5, Sellons-avenue, Harlesden, London, N.W., is the patentee.

HOSPITAL ABUSE, A SIDE THAT IS SOMETIMES OVERLOOKED."

To the Editors of THE LANCET.

SIRS,—The letter of your correspondent "Hospital Surgeon" in THE LANCET of Nov. 3rd (p. 1320), expressing openly, as it does, what are, I believe, the general, though somewhat thinly veiled, opinions of his class, seems to call for some reply from the general practitioners who have been educated and approved by examination by him or such as him. The general practitioner's rôle is stated to consist in "draining" a patient's "fee-paying capacity by a long course of useless medical treatment" He is further taxed with only sending for consultation "the refuse of his practice" or the "patients of whom he is weary or who are weary of him." We are further led to suppose that he has no therapeutic expedient beyond "the usual bottle of medicine." I am not concerned to answer these charges. I only wish to call attention to them as showing the opinion held by a hospital surgeon of those whom he lets loose on society and is thus responsible for. "'It was a thousand pities,' said Corporal Trim, 'though I believe, an' please your honour, that I am going to say but a foolish kind of thing for a soldier.' 'A soldier,' cried my uncle Toby, interrupting the corporal, 'is no more exempt from saying a foolish thing, Trim, than a man of letters.' 'But not so often, an' please your honour,' replied the corporal. My uncle Toby gave a nod." A general practitioner is no more exempt from making a mistake than a hospital surgeon, but not such a tragic one. Is not each class too apt to regard the other as a somewhat blundering rival rather than as a *confrère* practising an equally honourable branch of the profession and equally liable at times to err, in practice, in ethics, in brotherly feeling?

I am, Sirs, yours faithfully,
Nov. 5th, 1900. A GENERAL PRACTITIONER.

A QUESTION OF TASTE AND POLICY.

A (a registered medical practitioner) gives B and Co. a testimonial concerning their beef extract, &c. B and Co. ask permission to publish it and A gives them permission. Has A committed any offence against any law, rule, or regulation either of the General Medical Council or other governing body, either in giving the testimonial or in permitting it to be published?

The above question has been propounded to us by a subscriber and deals with a subject which has often been noticed by us in our columns. We take it for granted that our correspondent is describing the whole transaction and that no money has passed between A and B and Co. in return for the testimonial and that A was not interested in the sale of B and Co.'s commodity. A has not committed any offence against any law or any regulation of the General Medical Council, but what he has done is most inadvisable. On grounds of public policy it is a pity that testimonials should be given which to the censorious will always suggest that they have been given in return for value received, while on grounds of taste it is inadvisable that a medical man should have his name published abroad as an expert in food or allied subjects.

WHEAT GLUTEN FLOUR.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you or any of the readers of THE LANCET can supply me with the names and addresses of manufacturers in this country of wheat gluten flour.

I am, Sirs, yours faithfully,
Nov. 5th, 1900. R. A. B.

"MOTOR CARS FOR MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—If your correspondent "Motor-car" will emerge from the [illegible] of his *nom-de-plume* and meet me in the correspondence [illegible] of the *Autocar*, where we can more fitly discuss technicalities [illegible] relieve you of an interesting, though "foreign," argument, [illegible] very pleased to give him any details concerning my experience [illegible] he may wish to have. At the present moment he does not [illegible] er he is judging and condemning autocars as a *practical* [illegible] merely from the point of view of the man in the street.

MACGUIRE
Officer for
MACQUARIE, J.
Officer, Wi
MAUDSLEY, N.,
Officer Roth
MOORHEAD, JOHN
cian to the Roy

Curiously enough I gave up my horse and trap for the very same reasons that your correspondent hesitates to adopt the more modern mode of locomotion—viz., uncertainty, expense, and general unsatisfactoriness. It used to cost me about 6*d.* per mile in the days of the hay motor, whereas I ran up to London not long ago with another passenger and luggage on board my car for 7½*d.* (40 miles). If your correspondent should happen to be a resident in this town or neighbourhood it might interest him to attend the meeting of our club on Friday, Nov. 9th, when we propose to open a discussion upon the "Most Suitable Form of Motor Vehicle for General Purposes."

I am, Sirs, yours faithfully,
CLAUDE A. P. TRUMAN, L.R.C.P. Edin.,
Honorary Secretary Reading Automobile Club.
Reading, Nov. 6th, 1900.

THE EXTRACTION OF TEETH FOR CLUB PATIENTS.

To the Editors of THE LANCET.

SIRS,—I shall be very pleased if you or any of your readers will kindly inform me whether it is customary for club surgeons to extract teeth gratuitously for members. This may seem a small matter, but in a country practice extractions are numerous, and as dentistry is quite a separate branch I cannot see that it need be included under the head of "Medicines and Medical Attendance." It appears to me that if we do this club members may just as reasonably expect us to stop teeth and even to perform other and more difficult operations which belong entirely to the dental specialist. I have always charged and been paid for extractions, but I find that some clubs in the neighbourhood have squeezed these in under the elastic heading of "Medical Contract."

I am, Sirs, yours faithfully,
Nov. 6th, 1900. JUNIOR.

"WANTED—A HOME."

To the Editors of THE LANCET.

SIRS,—In answer to Dr. Herbert Hart's query in THE LANCET of Nov. 3rd the National Association for Promoting the Welfare of the Feeble-Minded (Office, 53, Victoria-street, S.W.) has training homes for children of weak mind not certifiably imbecile. Terms from 7*s.* to 10*s.* per week.

I am, Sirs, yours faithfully,
Richmond-hill, Surrey, Nov. 6th, 1900. G. E. SHUTTLEWORTH.

◆

Perplexed would be thankful for suggestions for treatment of the following cases. 1. Pruritus ani et scroti in a patient aged 25 years; generally worse at night. Many remedies have been tried, but relief has so far only been of a transitory nature. 2. Tinea sycosis, which has resisted treatment of various kinds for over six months.

M.B.—We cannot find upon the Register or in the Medical Directory the name of the medical man who gives the testimonial to the quack remedy. The testimonial is not fully dated. Of course it would be wrong for a medical practitioner to give such a testimonial.

E. M. W.—No connexion is known to exist between cancer and alcoholic abuses. Local irritation is stated to cause cancer of the lip in smokers but the predisposition must be very slight.

ERRATUM.—In THE LANCET of Nov. 3rd, p. 1306, col. 1, line 10 from foot, the word "gypsum" ought to have been *alum*.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received: *Catholic Times (London), Gainsborough Leader, Scarborough Mercury, Birmingham Daily Post, Farm, Field, and Fireside (London), Burton Mail, Dundee Advertiser, Glasgow Evening News, Leicester Daily Post, Bradford Observer, Westmorland Gazette, East Anglian Daily Times, Liverpool Daily Post, Darwen News, North British Daily Mail, Sheffield Daily Telegraph, York Daily Herald, Hereford Times, Scotsman, Citizen, Yorkshire Post, Times of India, Pioneer Mail, Builder, Architect, Bristol Mercury, Huddersfield Examiner, Science Siftings, Spare Moments, The Sun, Sanitary Record, Local Government Chronicle, Reading Mercury, City Press, Hertfordshire Mercury, Abingdon Herald, Dunfermline Press, Torquay Times, Sheffield Daily Telegraph, Daily Express, Hampshire Independent, Mining Journal, Surrey Advertiser, North China Daily*

News (Shanghai), Local Government Journal, Skyrack Courier (Leeds), South-West Suffolk Echo, Colchester Journal, Eastbourne Gazette, Lincoln Echo, Banbury Guardian, Wolverhampton Chronicle, Midland Counties Herald, South London Press, Horncastle News, Public Health, Cape Register, Licensed Victuallers' Gazette, Sleaford Journal, Leeds Mercury, Carnarvon Herald, Worthing Intelligencer, &c., &c.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.)

TUESDAY (13th).—London (2 P.M.), St Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (14th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (15th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (17th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (12th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Cases:—Dr. Cautley: Bi-lateral Birth Palsy.—Mr. Kellock: Mollities Ossium in a Child.—Dr. Caley: Vascular Swelling connected with the Thyroid.—Mr. Weeks: Congenital Locomotor Ataxy.—Dr. Dockrell: (1) Hyalin Degeneration of the Skin; (2) Adenoma Sebaceum.—Dr. Savill: Erythro-melalgia (Acroparæsthesia).—Mr. Wallis: Baker's Cyst of Leg (?) Mr Little: Specimens from a Case of Late Rickets shown at a previous meeting

TUESDAY (13th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.)—Dr. A. H. N. Lewers: The After Results in 40 Consecutive Cases of Vaginal Hysterectomy performed for Cancer of the Uterus.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury square, W.C.)—8 P.M. Mr. F. Browne: The Experiences of a British Pharmacist in China (illustrated by lantern slides).

WEDNESDAY (14th).—HUNTERIAN SOCIETY (London Institution, Finsbury circus).—8.30 P.M. Paper.—Dr. T. G. Stevens: Some Points in the Diagnosis and Treatment of Puerperal Sepsis

THURSDAY (15th).—*CHILDHOOD SOCIETY* (Library of the Sanitary Institute, 72, Margaret-street, W.)—8 P.M. Prof. W. H. Woodward: The Training of Teachers.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.)—8.30 P.M. Dr. R. Maguire: The Prognosis and Treatment of Tuberculous Disease of the Lungs. (Harveian Lecture.)

FRIDAY (16th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (Evelina Hospital, Southwark bridge-road, S.E.).—5.30 P.M. Cases will shown by Dr. Carpenter, Dr Chaffey, Dr. Sunderland, Mr. Tubby, Mr. Lucas, and Mr. Edmunds. Papers:—Dr. T. Fisher: Cases of Thrombosis of the Cerebral Veins in Children.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Dr. Patrick Manson (President): Some Problems in Tropical Epidemiology. (Inaugural Address.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Morris: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Beddard: Diet in Health and Disease.

TUESDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Dr W. Ewart: Consultation. (Medical.)

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars)—5 P.M. Mr. G. Pernet: Differential Diagnosis of Syphilitic and Non Syphilitic Affections of the Skin.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND—(Museum of Practical Geology, Jermyn-street, S.W.)—8.30 P.M. Right Hon Lord Avebury: Huxley Memorial Lecture

WEDNESDAY (14th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.)—5 P.M. Mr. W. H. A. Jacobson: Clinical Lecture. Some Remarks on the Question of Early Operation in Acute Appendicites

LONDON THROAT HOSPITAL (204, Gt. Portland street, W.)—5 P.M. Dr Woakes: Nasal Polipus with special reference to its recurrence. (Post-graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton)—4 P.M. Dr. Horton Smith: Bronchiectasis.

THURSDAY (15th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Mr. Hutchinson: Consultation. (Surgical.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W.C.).—4 P.M. Dr. Lees: Demonstration of Selected Cases.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL (Gray's Inn-road, W.C.)—5 P.M. Dr D. Grant: Diagnosis of Diseases causing Stridor or Obstruction to Respiration.

CHARING CROSS HOSPITAL.—4 P.M. Dr. Ellen: Gynæcological Demonstration. (Post graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.)—5 P.M. Dr. S. Taylor: Surface Anatomy.

FRIDAY (16th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—2-3.30 P.M. Dr. J. Taylor: Class. Clinical Examination of the Nervous System. 4 P.M. Dr. J. D. Grant: Consultation. (Ear.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have *the Proprietors* any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

we shall note that at the moment of injury numerous small vessels are ruptured and there is an instantaneous pouring out of a certain amount of blood and of lymph, so that effusion goes on for three or four hours after an injury. It is during these hours that the application of cold is so effective, and it seems to me that it acts in the following direction. It is a local constringent of the vessels, lessening their size and limiting the effusion. Now, if the amount of effusion poured into and around the joint be controlled the time of healing is lessened, and the probable amount of stiffness afterwards is also decreased, so that the patient recovers sooner. It is therefore quite rational to apply cold during the first three or four hours after the accident, and, indeed, it is the best method at our command. If there be a desire to check further the amount of effusion this can be readily done by the application of pressure and placing the joint in such a position that its potential cavity is lessened. For example, the knee should be placed in extension and not flexion, the ankle at a right angle and not in full extension nor in full flexion. Pressure is usually applied by bandage, but herein there is an intelligent and a non-intelligent method. If an ordinary bandage merely be bound round the joint the chief part of the pressure is made on the prominence of bones at the joint, but pressure must be made so that it is brought to bear evenly on all parts of the capsule which can be got at. For example, in the case of the ankle-joint a bandage around the ankle merely presses on the external and internal malleoli and on the tendo Achillis behind. But, now, if three or four layers of cotton-wool be placed on the joint with a little additional amount in front of and behind the internal and external malleoli and the bandage be then applied, the cotton-wool sinks into the various hollows and effectually compresses the distended capsule. So that if the sprain be seen within the first two or three hours of its occurrence the following treatment should be carried out. Apply cold vigorously for from about ten minutes to a quarter of an hour, either by pouring cold water over the joint or by the application of ice or spirit lotion and then wrap the joint round with lint or other suitable material soaked in cold water or spirit lotion, put on the cotton-wool in the manner just indicated and place the joint in such a position that there is least potential cavity for effusion to be poured into and firmly bandage the part.

During the period of quiescence the same line of treatment should be adopted, for there is some quiet effusion still going on. But when the second attack of pain ensues and it is becoming more severe, the application of cold is not of much value, since by this time the tissues are distended with blood and with lymph and effusion has now ceased to be poured out. The right thing to do is to apply heat, as hot applications not only diminish the pain but exercise a permanent effect upon the duration and the amount of swelling in this way; when the vessels which have been injured have recovered their tone the application of hot water or of heat in other forms promotes absorption, so that the effused blood and lymph are as rapidly as possible taken up into the blood-vessels and lymph-channels. During this time the joint should be kept at rest and pressure should be maintained on it by cotton-wool and a bandage, since well-directed pressure also assists absorption.

The most vexed question in connexion with a sprain is the duration of this period of rest. How long should it be persisted in? It may be said that as a rule most joints are rested too long and that at an average of three or four days after the swelling has subsided movement of the joint should be commenced. The direction of the movement is a most important point. It has already been stated that we can ascertain by the position of the tender spots and by the distribution of extravasated blood which part of the joint has been most injured. Take, for example, injury to the external lateral ligament of the ankle, no one would be so unwise as to invert the ankle as a part of the early movements, but would flex and extend and carefully evert it so that whilst moving the joint he would be in no way interfering with the healing of strained and of ruptured ligaments. It should not be forgotten that constitutional conditions influence the question of sprains very considerably. If the patient have a tuberculous history or a gouty or a rheumatic-gouty history he should rest much longer than should a patient with an ordinary history.

When the amount of swelling is very considerable hot applications and rest are not sufficient. The best thing is properly applied friction. The object of friction is to empty the lymphatics of a certain amount of coagulated lymph, and in rubbing the parts it is always adviseable to begin to rub that part of the swelling which is most distant from the joint, thus emptying the distant lymphatics first and then those which are nearer the joint and so promote circulation of lymph from the most congested to the least congested parts. Together with rubbing, frequent application of hot water and gentle movement should be carried out. If after ten days' treatment on these lines the thickening about the joint have not disappeared and there still remain tender spots on moving the articulation and on pressure, counter-irritation by blisters is called for. As a rule, one may say that in a fortnight or three weeks with the above treatment a severe sprain will cease to give rise to trouble and inconvenience and the patient can go about with comfort. Sometimes, however, it happens that on the patient attempting to use the joint acute pain sets in. This is due to sub-acute or chronic congestion of the joint, and the only treatment for it is absolute and complete rest. It is easily effected by means of a plaster-of-Paris application, and from four to six weeks is not too long a period to keep such a joint entirely at rest. It, however, frequently occurs that after the removal of the splint the movements are necessarily somewhat stiff and awkward and are not infrequently painful. As a rule, such pain does not arise from adhesions within the joint but it is really due to the condition of the muscles. They are at this stage somewhat wasted and their tendons are more or less glued in their sheaths. There are two means of overcoming these difficulties: one is by rapid movement of the parts under an anæsthetic and the other is by more gradual methods. The former, or the more forcible method, sometimes meets with astonishing success, but at other times it is followed by disaster, especially in cases with a tuberculous inheritance. The more gradual means comprise friction, the use of the hot-air bath, and the constant current. It is essential that patience in treatment should be inculcated, and if cases are treated on the above lines there will not, as a rule, be much difficulty in bringing even severe and complicated forms of sprain to a successful issue.

Allusion has been made in an early part of the paper to the practice of treating sprained joints by the method of mobility from the first. It is one which can only be employed in very slight cases and even then with some misgiving, for in certain patients the symptoms instead of rapidly clearing away become more pronounced and permanent thickening and disability of the joint remain.

II.—THE TREATMENT OF SOME FRACTURES.

The treatment of fractures about the elbow-joint.—Of all fractures those in the neighbourhood of this joint are more difficult to diagnose and are more often followed by disastrous consequences both to the practitioner and to his patient than any other fractures, and such was more often the case formerly than now that the Roentgen rays permit of early recognition of the mischief. But it must often happen that the rays are not available. Excluding fracture of the olecranon the general practice has been to put the arm up at a right angle with the forearm in the mid-position between pronation and supination. In my opinion keeping the limb in this position for a fortnight or three weeks is the cause of most, if not all, the after-trouble. Now I am about to propound an axiom—namely, that in all injuries about the elbow-joint except fracture of the olecranon the forearm should be forcibly extended, then supinated, then acutely flexed—that is to say, the limb should be placed with the ball of the thumb of the affected limb resting against the neck on the opposite side. No splint is needed and, indeed, is harmful, for the position can easily be secured by means of a sling passing round the neck and round the wrist. For the knowledge of this axiom and for an insight into its practical value I am wholly indebted to my friend Mr. Robert Jones of Liverpool.

It is interesting to see how it works out. Taking, for instance, a case of dislocation of the elbow backwards with fracture of the coronoid process of the ulna. If the limb be put up in the usual right-angled position the dislocation does not remain perfectly reduced, while the separated coronoid process is drawn upwards by the action of the brachialis anticus and acquires a new fixation point higher up on the ulna so that it locks prematurely in the coronoid fossa of the humerus and thus limits movement. Or, again, to take those severe injuries to the lower end of the humerus in which there is an oblique fracture into the joint with frequent displacement forwards of one of the condyles, if the limb is put up in the usual way at the right angle the displacement is not reduced, a large mass of callus is thrown out on the front of the humerus, and at the end of three or four weeks the range of movement is found to be limited to a few degrees and no efforts whether under an anæsthetic or not can increase this. If, however, as soon as possible after the accident the forearm be fully extended, and with the thumb pressure be firmly made in front of the elbow-joint and the forearm then acutely flexed and supinated and kept in apposition for the time mentioned above the result will be most satisfactory. What has happened is this. The ulnar and radial portions of the elbow-joint being in a flexed position have maintained the fractured parts of the bone in their proper position and by the pressure of the coronoid process into its fossa this depression has remained comparatively free from callus. It may be objected that there will be considerable difficulty in securing complete extension when the bones have been united, but it is a practical and therefore certain point that at the elbow after all fractures, except those of the olecranon, the difficulty arises not in obtaining extension but flexion movement, and it is this very difficulty which is obviated by the method of which I am speaking. To take one more example, a transverse fracture of the lower end of the humerus, if the right-angled position be adopted, the lower end of the upper fragment projects forwards and the lower fragment is displaced backwards. By adopting the acutely flexed position this is at once overcome. The same method is applicable to dislocations of the elbow after reduction, for if that position can be assumed there is no doubt that complete reduction has taken place. The value of the method might be exemplified in each of the many fractures in the neighbourhood of the elbow-joint, but space will not serve. Actual trial of the treatment of all doubtful injuries and fractures in the neighbourhood of this joint, except fractures *of the olecranon, by fully extending, then supinating the fore*arm and acutely flexing it without the subsequent use of splints, pads, and bandages, and merely using a sling, will prove the truth of these statements in a most gratifying way. At the end of from three to four weeks in the case of a fracture the hand should be dropped a little, and then two or three days afterwards it should be noted whether the patient can raise the forearm to the fully flexed position. If he can, the sling may be further loosened and the process repeated. If he cannot, the forearm must be placed back where it was previously and kept at rest there for some days and the experiment then be repeated.

Separation of the lower epiphysis of the femur.—This is a rare accident but there are many interesting points in connexion with it. The separated epiphysis is usually displaced forwards and not backwards, unlike the displacement which occurs in a transverse fracture of the lower end of the femur; the displacement is backwards almost always in the latter case. Forward displacement of the lower epiphysis is accounted for by this circumstance—the epiphyseal line is directed from the front downwards and backwards so that the epiphysis more readily glides forward on to the shaft. In transverse fracture the line of fracture usually passes above the attachment of the gastrocnemius; hence the fragment is tilted backwards. Another point of interest about separation of the epiphysis of the lower end of the femur is that it is almost always due to a wheel-accident, the most common cause being that a boy riding behind a cab gets his leg caught in the wheel and the epiphysis is wrenched off. There are two difficulties in treatment—first, to reduce the epiphysis and, secondly, to maintain the reduction. *This can sometimes be accomplished* by division of the tendo Achillis and forcible extension, but the epiphysis is extremely liable to become displaced. To prevent this Mr. Jonathan Hutchinson, jun., and Mr. H. L. Barnard recommend that the limb should be put up with the heel touching the buttock. I have made trial with both methods and have sometimes failed with them and been compelled to open the joint and to fix the epiphysis in place with a steel nickel-plated screw, and indeed this seems to me to be the best course to adopt in doubtful cases.

NEW ISOLATION HOSPITAL.—The Gelligaer District Council have decided to erect a permanent isolation hospital to take the place of three small cottages at present used for the purpose of isolation and the resources of which have proved totally inadequate during the epidemic of typhoid fever which is at the present time affecting the small mining village of Pontlottyn.

REMARKS ON TEN CASES OF ENTERIC FEVER IN WHICH THE BLOOD WAS EXAMINED PERIODICALLY FOR AGGLUTINATIVE PROPERTIES.

BY WILLIAM G. SAVAGE, B.Sc., M.D., D.P.H. LOND.,
LECTURER ON BACTERIOLOGY, UNIVERSITY COLLEGE, CARDIFF; BACTERIOLOGIST TO THE CARDIFF AND COUNTY PUBLIC HEALTH LABORATORY.

THIS investigation was undertaken mainly with the following objects: 1. *To determine as far as possible whether the* serum reaction is any aid to prognosis, and if any connexion between the serum reaction and the presence of complications, especially relapse, can be traced. 2. To determine whether the blood of patients suffering from enteric fever reacts better to the bacillus *coli communis* than the blood of patients not so suffering, and, if so, to see if the cases which so react run a different clinical course to the others, and if in such cases any causal connexion can be traced between this reaction and complications or relapse. 3. As a subsidiary *point, to* determine whether considerable differences in clumping power exist between typhoid bacilli obtained from different sources

It is now universally accepted that the bacillus coli communis is not a separate, distinct, and invariable organism, but rather that the name covers a group of organisms, closely allied but differing among themselves in certain details, chemical, morphological, and pathological. It is therefore *of importance that a number of bacilli coli obtained from* different sources should be used. The bacilli coli examined were derived from the sources shown in the following table:—

TABLE I.

Race of bacillus coli.	Whence obtained.
I.	Isolated from the stools of a patient suffering from enteric fever.
II.	Isolated from the urine in a case of pure bacillus coli infection *of some* part of the urinary system.
III.	The stock laboratory bacillus coli culture.
IV.	Obtained from a case of pyosalpinx.
V.	" " an abdominal abscess.
VI.	Isolated from the mesenteric glands in a case of enteric fever.
VII.	" " stools of a patient suffering from enteric fever.
IX.	" " stools of a patient suffering from enteric fever, Case 3 of the series.
X.	" " stools of a patient suffering from enteric fever, Case 9 of the series.
XI.	" " stools of a patient suffering from enteric fever, Case 3 of the series.
XII.	" " stools of a patient suffering from enteric fever, Case 9 of the series.
XIII.	" " *spleen* of a patient who died from enteric fever.
XIV.	" " milk (obtained from a farm) suspected of causing a small outbreak of enteric fever.

All of these except Coli III. were fairly recently isolated. Coli III. had been sub-cultured for over a year in the laboratory. It will be noticed that Coli I., VI., VII., IX., X., XI., XII., and XIII. were obtained from cases of enteric fever. They differed among themselves in rate of coagulation of milk, production of indol, &c. Only the pathogenic effects of Coli III. and Coli XIV. were tested. Coli III. is quite non-pathogenic even in considerable doses. Two cubic centimetres of Coli XIV. injected intra-peritoneally into a young rabbit caused death in about, or less than, 24 hours and the bacilli were isolated from the liver, spleen, peritoneal fluid, and heart blood. A variety of Gaertner's bacillus was also used on one or two occasions.

A number of typhoid bacilli isolated from different cases were also used. They will be indicated as follows:—Ty. St. (the stock laboratory culture), Ty. S, Ty. R, Ty. M, and

Ty. B—these last four were isolated from spleens of patients who died from enteric fever. All five of these races were obtained from different cases of enteric fever. Ty. S and Ty. St. were non-virulent even in considerable doses (i e., five cubic centimetres of young broth cultures injected intra-peritoneally into guinea pigs had no effect). Ty. R was isolated nine months before these observations were made, so probably it is non-virulent. It was not tested for virulence. Ty. M and Ty. B were both isolated in the autumn of 1899 and both showed a considerable degree of virulence The blood was collected from each case as far as possible every week and was stored till required in the ordinary sealed glass pipettes. The method of examination employed was in all cases the microscopic one. The diluted serum and broth (bacillus typhosus or bacillus coli) were mixed and a hanging drop preparation was made. The time allowed for the reaction to complete itself is of considerable importance. To insure comparable results in this particular the same time-allowance was given in each examination which was made. Very dilute sera require a considerable time to effect their specific action. Two hours is a convenient and fairly suitable period, and for all the following examinations this was the time-allowance. A number of control experiments were made with sedimentation tubes, but they are not included in the figures given in the paper. The dilutions were all accurately made by fine glass pipettes and in every case the diluting fluid consisted of 0·75 per cent. sodium chloride.

In comparisons between the agglutinative power of different sera it is exceedingly important that the conditions shall be comparable. This is probably often overlooked. Thus the age and nature of the typhoid culture used, the age of the culture from which it is a sub-culture, the temperature of incubation, and especially its degree of reaction (acidity or alkalinity), all may, and in some cases certainly seem to, affect the sensitiveness of the reacting typhoid culture. It is well known that the agglutinative power of any serum undergoes little or no deterioration by being kept. This was shown by Widal and others and incidentally I have been able to confirm this. To render the sera of the same case strictly comparable the tubes of blood collected week by week were not examined at once, but were kept until all the blood required was collected from that case. They were subsequently examined together so that the same broth culture of the bacillus typhosus or bacillus coli in question was, as far as possible, used for all the sera of that case. In this way differences of sensitiveness of culture &c., were quite excluded.

Broth cultures about 18 to 20 hours' old incubated at 37° C. were used in every case unless otherwise indicated. These broth sub-cultures were made from agar cultures from two to four weeks old and kept at the room temperature. The broth used was very faintly alkaline to litmus, and a large batch of broth tubes were made at once and kept specially for this work, so that for many of the different cases the same batch of broth was used. This question of comparable conditions is a very important one. In some cases, but practically almost entirely with Ty. S, Ty. St., and Coli III., a scum formed on the surface of the broth. These broth tubes were filtered through ordinary filter paper and the filtered solution (usually containing fewer bacilli) was used. These cultures also frequently showed pseudo-clumping (*vide infra*), and as special means were not infrequently required to obviate this the remark made above in regard to the exact comparability of the broth sub-cultures does not apply to all the cases where these cultures were used.

I have to thank Dr. S. Ringer, Dr. F. T. Roberts, Dr. G. V. Poore, and Dr. T. Barlow for their kind permission and for the facilities offered to me to examine the blood and record the clinical symptoms of the patients suffering from enteric fever under their charge in University College Hospital, London.

In considering the cases examined I will first deal with the question of serum prognosis From this point of view the reaction has been investigated by a number of observers, notably by Courmont,[1] who believes that valuable prognostic information may be obtained from repeated determination of the agglutinative power of the blood. He holds that in cases in which the agglutinative power rises as the temperature falls, falling again later in the disease, the prognosis is good, but that a bad prognosis must be given with a feeble reaction and in a case serious clinically, and also if the reaction is feeble at the height of the fever. A further conclusion is that a delayed serum reaction not appearing until after the seventeenth day is met with in the severe forms and in the very mild forms. Widal states that, as a general rule, the reaction is less marked in slight cases than in severe cases and is always less lasting after the defervescence, but he appears to think that the reaction is of but little use in prognosis. Catrin[2] thinks that the intensity and the early development of the reaction are in favour of a severe prognosis. The majority of observers, however, believe that little or no information in regard to prognosis can be obtained from the agglutinative power of the sera. Horton-Smith[3] says: "The only conclusion which can be drawn ...... is that no certain prognosis should be based on the intensity or the reverse of the serum reaction, and that consequently quantitative measurements except for diagnostic purposes are of but little value."

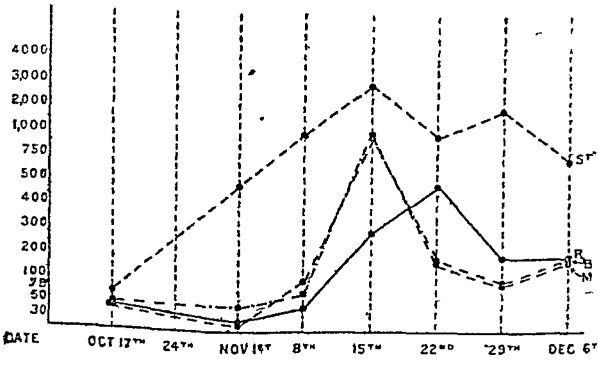
Is any such broad relationship between severity and reaction shown in the cases recorded here? As a general rule, does a marked reaction indicate a severe attack and a feeble reaction a mild attack? Or is the converse true, or is there no traceable connexion? Careful examination of the cases given below show no such broad general relationship. It is true that Case 2 and Case 8 were both mild cases and that in both of them only moderately marked reactions were obtained and also that Case 3, which was a well-marked case, gave very marked reactions at one period, yet, on the other hand, Case 4 and Case 7 were both severe and in both of these, on the whole, the reactions were not well marked. Also, considered in this broad way, under what category are we to place cases which at one time react very badly or not at all, while at other times they react markedly? The examination of these cases, therefore, confirms the more generally accepted opinion that the intensity of the reaction bears no relationship to the severity of the attack and is of no aid in giving a prognosis.

It is also of importance to find out whether any relationship exists, as Courmont believes, between the clinical course of the disease and the varying clumping power of the blood examined at different stages of the disease. The most graphic way to study this question is to make charts showing the highest dilution at which a positive reaction was obtained and then to compare these charts with the clinical features of the case. Weekly examinations of the blood were made and in most cases a number of different races of typhoid bacilli were used. The charts in Cases 1 to 9 were made in this way. For the chart in Case 10 the blood was only examined twice. The figures are made by joining the points which mark the maximum dilution giving a positive reaction in two hours. In the charts the vertical line of figures refers to the dilution of the serum employed and the horizontal to the date of examination. The several curves are made by joining the points giving a positive reaction with the highest dilution and are shown by different dotted lines for the different races of bacillus typhosus employed. The particular race used is indicated by lettering at the end of the curve, thus R=Curve obtained by using Ty. R, B=Curve of Ty. B, &c. The lines employed are indicated as follows: —— R, — — — — St or S, — - - - - - - B, —‖—‖—‖ M.

The following are brief clinical summaries of the cases:—

CASE 1.—The patient, a man, aged 30 years, was admitted into University College Hospital on Oct. 16th,

CHART 1.



The M curve in this chart is wrongly indicated by the illustrator. It should be indicated by —‖—‖.

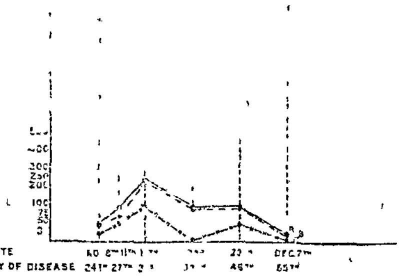
[2] La Semaine Médicale, 1896, p. 418.

[3] "Typhoid Bacillus and Typhoid Fever," Goulstonian Lectures, THE LANCET, March 24th (p. 821), and 31st (p. 910), and April 14th, 1900 (p. 1050).

1899, and was discharged on Dec. 8th The first symptoms occurred *about six weeks before admission* with violent pains in the abdomen. For the following three weeks the patient suffered from severe pain, sickness, and diarrhœa, and was confined to bed. Though he felt weak he then *resumed work and was at work* until Oct. 11th when pains in the abdomen and the side began. On admission the patient had a temperature of 104° F. which, however, rapidly declined and reached normal on Oct 22nd. On Nov. 3rd the temperature rose again and the patient apparently had a relapse The temperature went back to normal on the 21st. The temperature indicated a definite relapse, but there were no symptoms to account for the relapse and no fresh typhoid symptoms were exhibited Typhoid spots were present on admission, but not during the relapse The case was apparently not a severe one, the patient being admitted into the hospital towards the end of the attack.

CASE 2—The patient was a man, aged 21 years He was admitted into University College Hospital on Nov. 6th, 1899, and was discharged on Dec 8th His illness began about Oct 16th, three weeks before his admission, with a bad headache which lasted for a week There was some slight bleeding from the nose and the patient felt very ill. Diarrhœa and vomiting began later A few typhoid spots were found soon after admission. A little blood was passed in the stools during the course of the disease The temperature was 102·8° F. on admission and it reached its highest point (103·4°) on Nov. 8th. The temperature was quite normal from the 19th until the patient left the hospital. There were one or two actions of the bowels for the first few days after admission and they were subsequently produced by enemata This was a mild case of typhoid fever with only 13 days of temperature in the hospital and no complications.

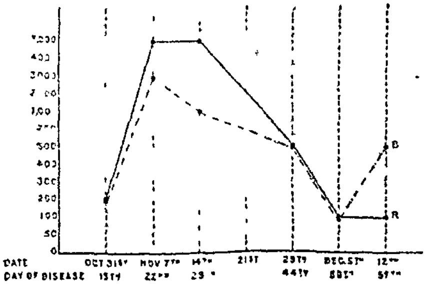
CHART 2



The st curve in this chart is wrongly indicated by the illustrator. It should be indicated by — — —. The curve of Ty. M is the same as the curve of Ty B.

CASE 3—The patient was a girl, aged 14 years. She was admitted into University College Hospital on Oct. 28th, 1899.

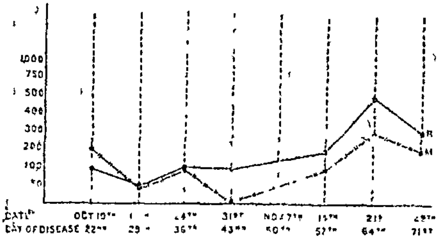
CHART 3.



The first symptoms, consisting of faintness, headache, and vomiting, appeared on Oct 17th and typhoid spots were first noticed on Nov. 1st. The temperature was 104·8° F. on admission and remained high until Nov. 2nd when it fell rapidly and reached normal on the 4th From the 5th to the 11th it was between 99° and 102° and it was practically normal from the 18th. The patient suffered from profuse diarrhœa which was most marked from Oct 30th to Nov 11th

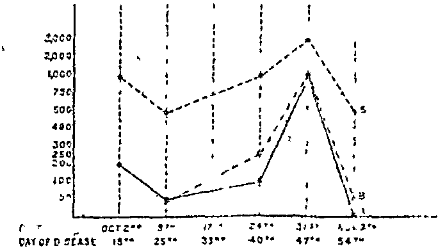
CASE 4.—The patient was a man, aged 27 years. He was admitted into University College Hospital on Sept. 26th, 1899, and was discharged on Dec. 4th. His illness began on Sept 19th with pains all over his body, loss of appetite, and slight headache On the 23rd he had to take to his bed and on the next day he had severe epistaxis When admitted he showed well-marked spots On Oct 17th the patient had a *rigor* and on the 13th and 14th he had profuse attacks of hæmorrhage from the bowel and lost altogether about three pints of blood. There was constipation throughout for which enemata were given. The temperature remained high until the middle of October and reached normal on the 24th On the 30th it rose again with pain and swelling of the left leg and it returned to normal by the middle of November On Oct 3rd and subsequently for a week the patient was very delirious and scarcely slept at all, his general condition being very bad The case was marked by a very profuse typhoid rash. Clinically this was a severe case with marked hæmorrhages and phlebitis.

CHART 4.



CASE 5—The patient was a man, aged 25 years He was admitted into University College Hospital on Sept 27th, 1899, and was discharged on Nov 15th. His illness began on Sept. 14th *with great pain in the loins, and on the third day there were violent hæmorrhage and vomiting* The patient's temperature on admission was 104° F, but it fell rapidly, and became normal on Oct 6th. It began to rise again on the 11th and a well-marked relapse then took place. It fell back to normal on the 28th, and this was maintained until the patient left the hospital on Nov. 15th The relapse was marked by fresh spots and the spleen remained enlarged. The relapse showed a typical "staircase" rise and fall of temperature There was constipation throughout. Clinically this was a moderately severe case

CHART 5.



CASE 6—The patient was a woman aged 29 years. She was admitted into University College Hospital on Oct. 30th, 1899 The first symptoms occurred on the 24th, when the patient had severe headache and pains in the back, and she remained in bed from the next day till she was admitted into the hospital Spots were not noticed till Nov. 4th The temperature from Oct. 30th to Nov. 3rd ranged between 101·6° and 104° F, from Nov 4th to the 11th between 100° and 102°, and from the 12th to the 17th between 99° and 101°. The temperature reached normal on the 18th and *remained so until the 21st.*

Ty. B—these last four were isolated from spleens of patients who died from enteric fever. All five of these races were obtained from different cases of enteric fever. Ty. S and Ty. St. were non-virulent even in considerable doses (i e., five cubic centimetres of young broth cultures injected intra-peritoneally into guinea pigs had no effect). Ty. R was isolated nine months before these observations were made, so probably it is non-virulent. It was not tested for virulence. Ty. M and Ty. B were both isolated in the autumn of 1899 and both showed a considerable degree of virulence The blood was collected from each case as far as possible every week and was stored till required in the ordinary sealed glass pipettes. The method of examination employed was in all cases the microscopic one. The diluted serum and broth (bacillus typhosus or bacillus coli) were mixed and a hanging drop preparation was made. The time allowed for the reaction to complete itself is of considerable importance. To insure comparable results in this particular the same time-allowance was given in each examination which was made. Very dilute sera require a considerable time to effect their specific action. Two hours is a convenient and fairly suitable period, and for all the following examinations this was the time-allowance. A number of control experiments were made with sedimentation tubes, but they are not included in the figures given in the paper. The dilutions were all accurately made by fine glass pipettes and in every case the diluting fluid consisted of 0·75 per cent. sodium chloride.

In comparisons between the agglutinative power of different sera it is exceedingly important that the conditions shall be comparable. This is probably often overlooked. Thus the age and nature of the typhoid culture used, the age of the culture from which it is a sub-culture, the temperature of incubation, and especially its degree of reaction (acidity or alkalinity), all may, and in some cases certainly seem to, affect the sensitiveness of the reacting typhoid culture. It is well known that the agglutinative power of any serum undergoes little or no deterioration by being kept. This was shown by Widal and others and incidentally I have been able to confirm this. To render the sera of the same case strictly comparable the tubes of blood collected week by week were not examined at once, but were kept until all the blood required was collected from that case. They were subsequently examined together so that the same broth culture of the bacillus typhosus or bacillus coli in question was, as far as possible, used for all the sera of that case. In this way differences of sensitiveness of culture &c., were quite excluded.

Broth cultures about 18 to 20 hours' old incubated at 37° C. were used in every case unless otherwise indicated. These broth sub-cultures were made from agar cultures from two to four weeks old and kept at the room temperature. The broth used was very faintly alkaline to litmus, and a large batch of broth tubes were made at once and kept specially for this work, so that for many of the different cases the same batch of broth was used. This question of comparable conditions is a very important one. In some cases, but practically almost entirely with Ty. S, Ty. St., and Coli III., a scum formed on the surface of the broth. These broth tubes were filtered through ordinary filter paper and the filtered solution (usually containing fewer bacilli) was used. These cultures also frequently showed pseudo-clumping (*vide infra*), and as special means were not infrequently required to obviate this the remark made above in regard to the exact comparability of the broth sub-cultures does not apply to all the cases where these cultures were used.

I have to thank Dr. S. Ringer, Dr. F. T. Roberts, Dr. G. V. Poore, and Dr. T. Barlow for their kind permission and for the facilities offered to me to examine the blood and record the clinical symptoms of the patients suffering from enteric fever under their charge in University College Hospital, London.

In considering the cases examined I will first deal with the question of serum prognosis From this point of view the reaction has been investigated by a number of observers, notably by Courmont,[1] who believes that valuable prognostic information may be obtained from repeated determination of the agglutinative power of the blood. He holds that in cases in which the agglutinative power rises as the temperature falls, falling again later in the disease, the prognosis is good, but that a bad prognosis must be given with a feeble reaction and in a case serious clinically, and also if the reaction is feeble at the height of the fever. A further conclusion is that a delayed serum reaction not appearing until after the seventeenth day is met with in the severe forms and in the very mild forms. Widal states that, as a general rule, the reaction is less marked in slight cases than in severe cases and is always less lasting after the defervescence, but he appears to think that the reaction is of but little use in prognosis. Catrin[2] thinks that the intensity and the early development of the reaction are in favour of a severe prognosis. The majority of observers, however, believe that little or no information in regard to prognosis can be obtained from the agglutinative power of the sera. Horton-Smith[3] says: "The only conclusion which can be drawn ...... is that no certain prognosis should be based on the intensity or the reverse of the serum reaction, and that consequently quantitative measurements except for diagnostic purposes are of but little value."

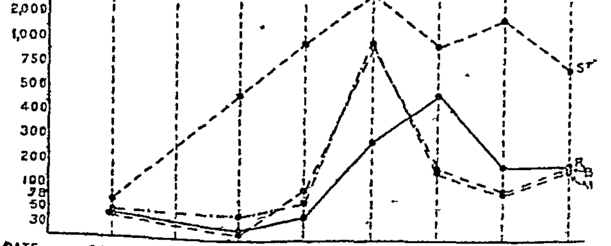
Is any such broad relationship between severity and reaction shown in the cases recorded here? As a general rule, does a marked reaction indicate a severe attack and a feeble reaction a mild attack? Or is the converse true, or is there no traceable connexion? Careful examination of the cases given below show no such broad general relationship. It is true that Case 2 and Case 8 were both mild cases and that in both of them only moderately marked reactions were obtained and also that Case 3, which was a well-marked case, gave very marked reactions at one period, yet, on the other hand, Case 4 and Case 7 were both severe and in both of these, on the whole, the reactions were not well marked. Also, considered in this broad way, under what category are we to place cases which at one time react very badly or not at all, while at other times they react markedly? The examination of these cases, therefore, confirms the more generally accepted opinion that the intensity of the reaction bears no relationship to the severity of the attack and is of no aid in giving a prognosis.

It is also of importance to find out whether any relationship exists, as Courmont believes, between the clinical course of the disease and the varying clumping power of the blood examined at different stages of the disease. The most graphic way to study this question is to make charts showing the highest dilution at which a positive reaction was obtained and then to compare these charts with the clinical features of the case. Weekly examinations of the blood were made and in most cases a number of different races of typhoid bacilli were used. The charts in Cases 1 to 9 were made in this way. For the chart in Case 10 the blood was only examined twice. The figures are made by joining the points which mark the maximum dilution giving a positive reaction in two hours. In the charts the vertical line of figures refers to the dilution of the serum employed and the horizontal to the date of examination. The several curves are made by joining the points giving a positive reaction with the highest dilution and are shown by different dotted lines for the different races of bacillus typhosus employed. The particular race used is indicated by lettering at the end of the curve, thus R=Curve obtained by using Ty. R, B=Curve of Ty. B, &c. The lines employed are indicated as follows: —— R, —·—·— St or S, — — — — — B, —‖—‖—‖ M.

The following are brief clinical summaries of the cases:—

Case 1.—The patient, a man, aged 30 years, was admitted into University College Hospital on Oct. 16th,

CHART 1.



The M curve in this chart is wrongly indicated by the illustrator. It should be indicated by —‖—‖.

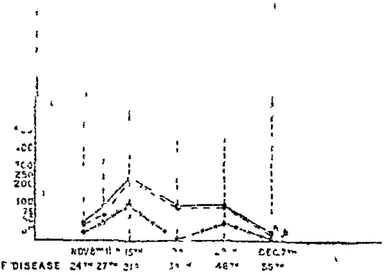
[2] La Semaine Médicale, 1896, p. 418.

[3] "Typhoid Bacillus and Typhoid Fever," Goulstonian Lectures, The Lancet, March 24th (p. 821), and 31st (p. 910), and April 14th, 1900 (p. 1050).

1899, and was discharged on Dec. 8th. The first symptoms *occurred about six weeks before admission* with violent pains in the abdomen For the following three weeks the patient suffered from severe pain, sickness, and diarrhœa, and was confined to bed. Though he felt weak he then resumed work and was at work until Oct 11th when pains in the abdomen and the side began. On admission the patient had a temperature of 104° F. which, however, rapidly declined and reached normal on Oct 22nd. On Nov. 3rd the temperature rose again and the patient apparently had a relapse The temperature went back to *normal* on the 21st. The temperature indicated a definite relapse, but there were no symptoms to account for the relapse and no fresh typhoid symptoms were exhibited Typhoid spots were present on admission, but not during the relapse The case was apparently not a severe one, the patient being admitted into the hospital towards the end of the attack.

CASE 2 —The patient was a man, aged 21 years He was admitted into University College Hospital on Nov. 6th, 1899, and was discharged on Dec 8th His illness began about Oct 16th, three weeks before his admission, with a bad headache which lasted for a week There was some slight bleeding from the nose and the patient felt very ill Diarrhœa and vomiting began later. A few typhoid spots were found soon after admission A little blood was passed in the stools during the course of the disease The temperature was 102 8° F. on admission and it reached its highest point (103 4°) on Nov. 8th The temperature was quite normal from the 19th until the patient left the hospital. There were one or two actions of the bowels for the first few days after admission and they were subsequently produced by enemata This was a mild case of typhoid fever with only 13 days of temperature in the hospital and no complications.

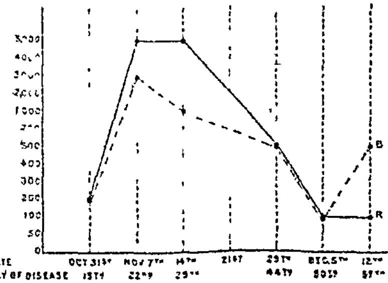
CHART 2



The st. curve in this chart is wrongly indicated by the illustrator. It should be indicated by — — —. The curve of Ty. M is the same as the curve of Ty B.

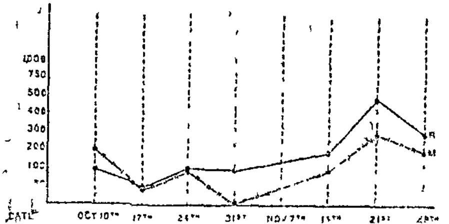
CASE 3 —The patient was a girl, aged 14 years. She was admitted into University College Hospital on Oct. 28th, 1899 The first symptoms, consisting of faintness, headache, and vomiting, appeared on Oct 17th and typhoid spots were first noticed on Nov. 1st. The temperature was 104 8° F. on admission and remained high until Nov. 2nd when it fell rapidly and reached normal on the 4th. From the 5th to the 11th it was between 99° and 102° and it was practically normal from the 18th The patient suffered from profuse diarrhœa which was most marked from Oct 30th to Nov 11th

CHART 3.



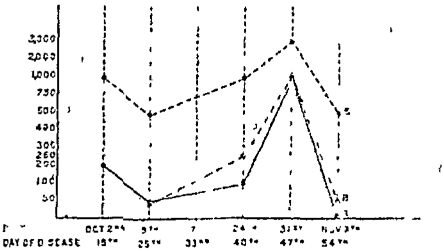
CASE 4 —The patient was a man, aged 27 years He was admitted into University College Hospital on Sept. 26th, 1899, and was discharged on Dec 4th. His illness began on Sept 19th with pains all over his body, loss of appetite, and slight headache On the 23rd he had to take to his bed and on the next day he had severe epistaxis When admitted he showed well-marked spots On Oct 17th the patient had a *rigor* and on the 13th and 14th he had profuse attacks of hæmorrhage from the bowel and lost altogether about three pints of blood. There was constipation throughout for which enemata were given The temperature remained high until the middle of October and reached normal on the 24th On the 30th it rose again with *pain and swelling of the left leg and it* returned to normal by the middle of November On Oct 3rd and subsequently for a week the patient was very delirious and scarcely slept at all, his general condition being very bad. The case was marked by a very profuse typhoid rash. Clinically this was a severe case with marked hæmorrhages and phlebitis.

CHART 4.



CASE 5 —The patient was a man, aged 25 years He was admitted into University College Hospital on Sept 27th, 1899, and was discharged on Nov. 15th. His illness began on Sept. 14th with great pain in the loins, and on the third day there were violent hæmorrhage and vomiting The patient's temperature on admission was 104° F., but it fell rapidly, and became normal on Oct 6th. It began to rise again on the 11th and a well-marked relapse then took place It fell back to normal on the 28th, and this was maintained until the patient left the hospital on Nov. 15th The relapse was marked by fresh spots and the spleen remained enlarged. The relapse showed a typical "staircase" rise and fall of temperature There was constipation throughout. Clinically this was a moderately severe case

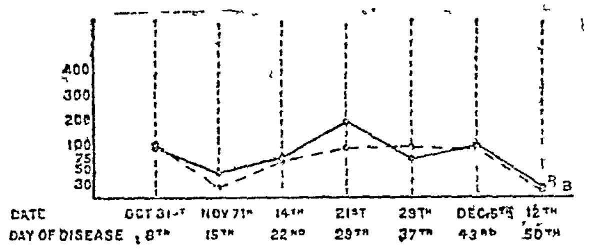
CHART 5.



CASE 6 —The patient was a woman, aged 29 years She was admitted into University College Hospital on Oct. 30th, 1899 The first symptoms occurred on the 24th, when the patient had severe headache and pains in the back, and she remained in bed from the next day till she was admitted into the hospital Spots were not noticed till Nov 4th The temperature from Oct 30th to Nov. 3rd ranged between 101 6° and 104° F., from Nov 4th to the 11th between 100° and 102°, and from the 12th to the 17th between 99° and 101°. The temperature reached normal on the 18th and remained so until the 21st.

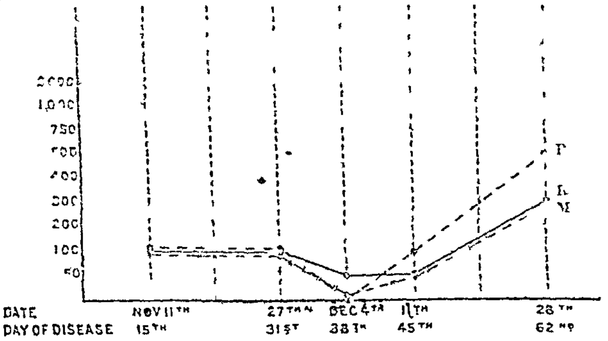
A relapse then began, and the temperature reached its maximum on Nov 30th, when it was 103·8°, and did not decline to normal till Dec. 15th, and this was maintained until the patient left the hospital. Constipation was present on admission and lasted until Nov 29th, but subsequently natural actions occurred.

CHART 6.



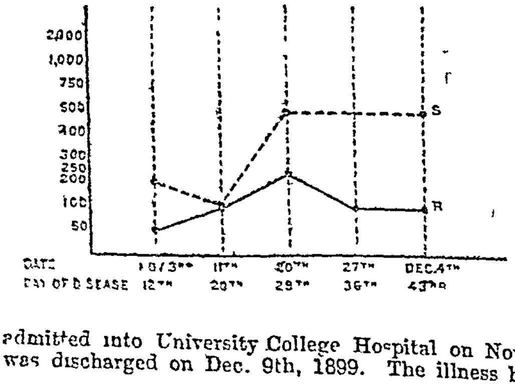
CASE 7.—The patient was a man, aged 29 years. He was admitted into University College Hospital on Nov. 6th, 1899. The disease began about Oct. 23rd with a severe attack of diarrhœa and later there were headache and pains in the limbs. The patient took to his bed a week after the onset of the diarrhœa. When admitted into the hospital his abdomen was slightly distended. There were no typhoid spots and the spleen was not to be felt There was nothing abnormal in the heart or in the lungs From Nov 7th to the 9th there was marked and violent delirium. On the 19th swelling of the left parotid began, and on the 24th an incision was made and a little pus was evacuated. The pus contained only staphylococci and streptococci; there were no typhoid bacilli The temperature, which was 103° F. on admission, gradually came down and was normal by the 14th. It rose again on that day owing to the parotid swelling, but fell again to normal by the 29th, again rising on Dec 1st and rapidly reaching 103·2°. The next day it again began to decline, showing a typical "staircase" chart, and reached normal on the 6th No fresh spots were noticed and nothing was found to account for the rise of temperature. On Nov. 10th the temperature went up and the patient had a succession of rigors. On Dec 17th he complained of pain in the left groin and swelling of the left calf. He had three natural actions on Nov. 10th and 11th, but since that time his bowels were relieved by enemata.

CHART 7.



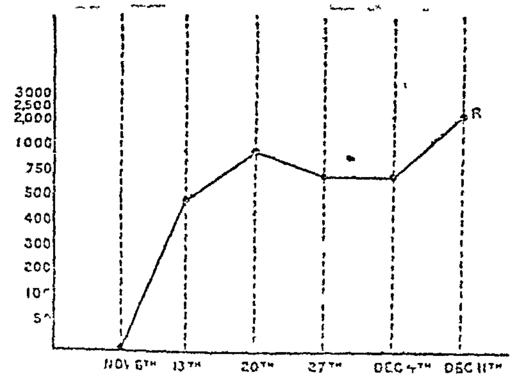
CASE 8.—The patient was a woman, aged 31 years. She was admitted into University College Hospital on Nov. 1st and was discharged on Dec. 9th, 1899. The illness began at the end of September with loss of appetite and of sleep. The woman became very weak and was unable to get about, but she did not take to her bed until she was admitted into the hospital. Typhoid spots were first noticed on Nov. 5th. For the first week after admission the temperature was up to 104° F. during some part of the 24 hours, but gradually fell during the next week, and remained practically normal from the 14th. No complications ensued and the patient made an uninterrupted recovery. Her bowels were at first constipated, but on and after Nov 10th they acted naturally.

CHART 8.



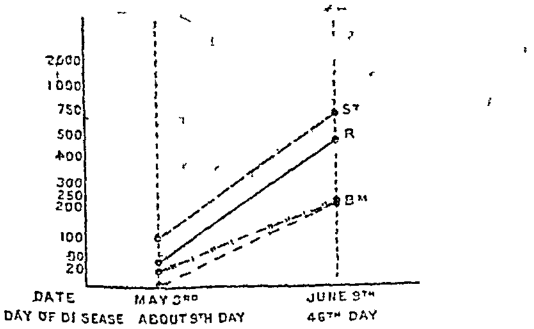
CASE 9.—The patient was a woman, aged 30 years. She was admitted into University College Hospital on Nov. 1st, 1899. The illness began three weeks before her admission into the hospital with severe headache. She had feverish attacks, with alternate fits of heat and cold and sweating at night. She was treated for rheumatism. On admission she had pains in her ankle-joints. On Nov. 6th typhoid spots were found and the patient passed a typical typhoid stool. A little blood was passed in the stools on the 7th and the 9th and again on the 23rd and the 25th. The patient had diarrhœa for the first week after admission and maintained a fairly free action of the bowels throughout the attack. Until Nov. 30th the temperature remained high; it then began to decline and on Dec 3rd it reached normal. This was a well marked case in which the general condition of the patient was good and in which, with the exception of slight hæmorrhage on two occasions, there were no complications

CHART 9.



CASE 10.—The patient was a man, aged 30 years. He was admitted into Cardiff Sanatorium on May 2nd, 1900, and was discharged cured on July 12th. He had taken to his bed about April 24th. On admission the rash was very marked. A relapse began about May 27th, the maximum temperature being reached on June 1st, but it declined to normal on the 17th. A fresh crop of spots developed during the relapse.

CHART 10.



We can now see if any relationship can be made out between any of the symptoms or complications and the serum reaction The serum reaction and temperature charts will first be considered. The cases unaccompanied by any complications are of special interest from this point of view. These are Case 2, Case 3, and Case 8. In all of these three cases there was a gradual or a rapid fall of temperature which did not rise again. In all three cases the reaction was not at its maximum at the same time as the temperature but was best marked when the temperature was falling or after it had reached normal Later the agglutinative power fell also. According to Courmont this association indicates a good prognosis Case 2 and Case 8 were mild cases and Case 3 was a well marked but not severe, case in a child The patients in all the three cases made a good recovery In the main, therefore, these three cases agree with Courmont's dictum In the other cases complications were present and any possible relationship was therefore obscured Thus in Case 1 the reaction was *only* well marked *after* the relapse and was best marked when the temperature was falling In Case 4 the highest positive reaction was obtained after the temperature had been normal, or nearly normal, for four weeks. In Case 5 the reaction curves appeared to come down with the temperature, rising again when the relapse began, but reaching their highest point considerably later than the maximum temperature of the relapse In Case 6 the reactions were feebly marked throughout and in Case 7 the numerous complications prevented any connexion being traced In Case 9 the clumping power gradually rose while the temperature remained high and it continued well marked after the temperature had returned to normal The highest positive reaction was obtained after the reaction had become normal.

In the second place, the relationship to complications is worth investigating, and of these relapse possesses the greatest interest Relapses were met with in Case 1, Case 5 Case 6, and Case 10 In Case 7 a rise of temperature took place which was very suggestive of a relapse, but no true reinfection, in the sense of fresh spots, occurred and its duration was very short The fall of the temperature was very suggestive No obvious explanation of this rise of temperature was noted and at the most it can be considered as a very doubtful case of relapse That relapses were met with in four (? five) out of 10 cases is easily to be explained, because Case 10 was only selected on account of its relapse while the other three relapses occurred in a series of cases much greater than nine but in which only nine were carefully worked out, the blood collected from the other cases being only partially utilised In all these cases of relapse the following peculiarity is noticeable—i e, in all, at one period or other, before the relapse the blood reacted very feebly or not at all[4] This can be seen from the serum charts and also in Table II

TABLE II

Case	Relapse		Remarks on the serum reaction
	Date of onset	Day of disease	
1	Nov 3rd	Twelve days after the temperature had reached normal.	Both examinations before the relapse (Oct 17th and Nov 1st) showed only weak reactions Subsequently the reactions became well marked
5	Oct 11th	Twenty seventh	Two days before the relapse the blood would only react 1 in 50 with Ty M Ty B and Ty R. Subsequently the reaction became well marked
6	Nov 21st.	Twenty ninth	Two weeks before the relapse the reactions were very feebly marked and they were not well marked a week before the relapse There was no subsequent well marked reaction
10	May 27th.	About the thirty third	The blood was only examined twice The first examination three and a half weeks before the relapse showed feeble reactions The second examination during the relapse (13 days after its commencement) showed well marked reactions

Is the converse true? Do all cases with a feeble reactive power relapse? In the series of cases recorded here this is certainly not the case This can be readily seen from the charts To give only one example—In Case 2 the blood was first examined on Nov 8th, and here, with Ty B, Ty R, and Ty St no positive reaction was obtained with a greater dilution than 1 in 50 In the relapse cases, except in Case 1, we have a *fall* in the agglutinative power of the blood previously to the relapse The patient in Case 1 came into the hospital towards the end of the attack, and a slight fall is noticed It is not unreasonable to suppose that if the serum could have been examined earlier a more marked agglutinative action would have been demonstrated If so it would bring it into line with the other cases This fall and subsequent rise again in the other case is only present in Case 4 and Case 7 In Case 7 there is considerable evidence of a relapse of an abortive nature starting on Dec 1st If the condition is a true relapse then this fall must be considered along with that of Case 5 and Case 6 In Case 4 the patient had several severe attacks of hæmorrhage, which took place on Oct 13th and 14th The fall of agglutinative power was noticed when the blood was examined three days later. It seems not unreasonable to attribute this fall to the severe hæmorrhage which would, one would expect, diminish the quantity of agglutinins in the blood The fact that here we have severe hæmorrhage on Oct 13th and 14th with a fall of agglutinative power, and that the agglutinative power of the blood subsequently rises, is of great interest when considered with Gengou's conclusion that if an animal be bled the agglutinative power falls and does not rise again Contrary to this observer in this case, apparently, the fall due to bleeding was associated with a subsequent rise, and this is rather what we would expect and further illustrates the close parallel between antitoxins and agglutinins

Considering, therefore, all the cases we may say that the cases which relapse show at some period previously to the relapse very feeble agglutinative properties and that very generally these weak reactions are preceded by better marked reactions, yet, on the other hand, it is in no way true to infer that all cases which show a feeble serum reaction will relapse From so few cases it is futile to lay down definite rules, but stating the matter in another way we are, perhaps, justified in saying that if the blood examined every week shows a well marked *reaction* no relapse is to be anticipated, but if a feeble reaction is obtained relapse may follow, and this is especially likely to occur if on previous examination the reaction had been better marked

A number of observers have recorded cases where, following failure to obtain a positive serum reaction, relapse has followed Widal records a case with no serum reaction in the original attack Park also records a similar case Elsberg[5] includes four cases of relapse in his series In the first case the reaction appeared on the sixteenth day, in the second on the twenty fourth day, in the third on the twenty seventh day, and in the fourth on the thirty second day In one case the reaction only appeared during the second relapse *In these cases the reaction in those which relapsed* was delayed Very possibly some slight but incomplete reaction was present earlier Cabot[6] mentions three cases in which he obtained the reaction only in the relapse and quotes cases by other observers Lately Dr H P. Hawkins and Dr E O Thurston[7] have recorded a case with a negative serum reaction on the fifteenth day, the twenty second day, and the thirty seventh day, but a positive reaction on the one hundred and third day, the positive reaction only being obtained after the onset of a relapse These cases all confirm the evidence that previously to a relapse there is a diminished agglutinability of the blood

Of the theories of relapse perhaps the most generally accepted one at the present day is that it is a re infection by the typhoid bacillus, by bacilli already in the body, the re infection being possible owing to poorly acquired immunising properties and precipitated by the absorption of toxins from the alimentary canal increasing the virulence of the typhoid bacillus This view is very clearly stated by Dr Horton Smith[8] According to this view several factors two at least, seem to be necessary for a relapse to take place The blood must be so modified that it permits a re infection and the virulence of the typhoid bacilli requires raising As Professor A E Wright and Captain G Lamb I M S,[9] say, "The agglutinins are bacteriotropic and anti bacterial substances," and if this be so a low clumping power would seem to be one of the factors which should enable a relapse to take place It is well known from Courmont's researches that if the typhoid bacillus be grown in a medium containing typhoid serum the agglutinins disappear in proportion to the growth of the bacilli or stating it in another way, as Professor Wright and Captain Lamb put it, 'the typhoid bacillus cultivates itself in a medium which is relatively poor in agglutinins' *A low agglutinative power of the blood would certainly seem to favour re infection*

It is obvious that the low agglutinative power of the blood is not all that is necessary for a relapse to occur because feeble serum reactions are present in many cases which do not relapse. There must be other factors at work. Fresh virulence of the typhoid organism brought about by absorption of toxins from the alimentary canal is, in the view stated above, assumed to be the most important other factor. That the cause of this fresh virulence is the absorption of the bacillus coli toxins from the alimentary canal obtains no support from my cases, for the cases which relapsed gave no reaction with bacillus coli greater than the non-relapsing cases though several examinations were made both before and after the relapse began. This can be seen from Table III. In fact, excluding Coli III., no positive reactions were met with.

---

[4] A serum which gives a negative reaction in two hours with a dilution of 1 in 30 is considered not to react.

TABLE III.

Case.	When the examinations were made.	Race of bacillus coli examined.	Dilution employed.	Results.
5	Two days before commencement of relapse.	I., II., III., IV., V., VI., VII.	1 per cent.	Coli III. weak + reaction. Others give negative reaction.
	20 days after commencement of relapse.	I., II., III., IV., V., VII., IX., XII., XIII.	1 in 50	Coli III. weak + reaction. Others give negative reaction.
6	Three weeks before commencement of relapse.	I., II., III., IV., V., VI.	1 per cent.	No reaction.
	One week before commencement of relapse.	I., IX., XII., XIII.	1 in 50	" "
	Two weeks after commencement of relapse.	I., II., IV., V., VI., IX., XII., XIII.	1 in 50	" "

The date of the disease in regard to the time when the reaction was best developed is given in Table IV.

TABLE IV.

Case	Date of disease when reaction was most marked.	Relation of maximum reaction to onset of the relapse.
2	About the fifth week.	—
3	Fourth week.	—
8	End of the fourth week.	—
1	About the seventh to the eighth week.	From two to three weeks after the relapse.
5	Seventh week.	About three weeks after the relapse began.
6	Third to the sixth week.	From a week before and two weeks later than the onset of the relapse.

It is difficult to give a definite date for the other cases not given in Table IV. From this table we see that in the three cases without any complication (Case 2, Case 3, and Case 8) the reaction was best marked about the end of the fourth or fifth week. In the other cases it was best marked after the relapse. In regard to complications other than relapse no special relationship is traceable, nor indeed would any be expected. It is of greater interest to consider these cases in regard to possible bacillus coli infection.

The second object of these investigations was to ascertain whether the blood of enteric fever patients reacted to bacillus coli communis and to elucidate if possible the significance of such reactions. The question of bacillus coli reactions in typhoid fever seems to be a difficult one, and one on which there is great diversity of opinion, observation, and experiment. Courmont[10] finds that the serum of typhoid fever gives a partial positive reaction with bacillus coli, using the same dilution as for bacillus typhosus. He says that the reaction is occasionally more intense with bacillus coli than with bacillus typhosus. Chantemesse[11] obtained negative results. Durham,[12] working with artificially prepared animal sera, found that the blood of animals immunised against bacillus typhosus did not agglutinate bacillus coli races though he obtained well-marked agglutinative effects with bacillus coli in animals immunised against that bacillus. Johnston,[13] working with dried blood, found positive colon reactions in some cases. He says: "A complete colon reaction we have found to be exceptional in ordinary typhoid, and its presence would indicate a condition of coli intoxication sufficient to explain the existence of many symptoms giving to typhoid its ordinary clinical features." Lorrain Smith and Tennant[14] found distinct evidence of bacillus coli reactions, using bacillus coli obtained from the local water-supply and from the spleens of the patients in certain typhoid fever cases and they raise the question of a secondary infection by bacillus coli in cases of enteric fever. In the case of the allied Gaertner's bacillus it seems to be generally admitted that the blood in many, though certainly not in all, cases of typhoid fever contains Gaertner agglutinins. Some of the cases in which bacillus coli agglutinated typhoid sera may no doubt be explained by insufficient dilution of the blood, or possibly the pseudo-clumps occasionally met with in cultures of bacillus coli may not have been guarded against, for, as Stern[15] has pointed out, spontaneous clumping is not infrequently met with in bacillus coli cultures, while Christophers[16] has shown that with low dilutions non-typhoid and typhoid sera will agglutinate bacillus coli very frequently and even in some cases with a dilution of greater than 1 per cent.

A number of different bacillus coli races were tested with sera from typhoid fever cases and from non-typhoid cases (nearly all in 1 per cent. dilution). In all the sera of 15 typhoid fever cases were examined. The result is given in Table V., which shows the reactions of bacillus coli in typhoid fever cases. All the dilutions were 1 per cent. unless otherwise stated.

TABLE V.

Race of coli bacillus.	Number of different cases examined	Number of different specimens of blood examined.	Number of positive reactions.	Number of negative reactions.
I.	12	24	0	24
II.	7	10	0	10
III.	15	33	17 (1 per cent.), 1 (1 in 50)	15 (3 tested 1 in 50)
IV.	9	11	0	11
V.	9	11	0	11
VI.	9	11	0	11
VII.	5	7	0	7
IX.	8	13	0	13
X.	3	5	0	5
XI.	1	5	2*	3
XII.	7	12	0	12
XIII.	8	15	0	15
XIV.	2	3	0	3

* Only partial reactions.

From this table it will be seen that 11 out of 13 different bacilli coli failed to react in 1 per cent. dilution to any of the typhoid sera, though they were tried in a good many cases and not infrequently on several occasions. Coli XI. gave a partial positive reaction twice out of five examinations in the only case (Case 2) examined. As it was only examined in one case and only partial reactions were obtained I have excluded it from further consideration. The cultures died out and so no further examinations were possible. Coli III. gave a majority of positive reactions. Can the fact that Coli III. reacted in such a high percentage of cases be taken as any evidence that typhoid fever blood has a special action on the bacillus coli? The reaction of this variety of bacillus coli to non-typhoid sera must be considered. Some figures are given in Table VI., which shows the reactions of Coli III. to non-typhoid sera.

TABLE VI.

Source of the serum.	Dilution 1 in 100.	Dilution 1 in 50.	Dilution 1 in 20.
Normal blood (P)	—	—	—
Case of empyema (said to have had typhoid fever five months previously)	—	+	—
Case of tuberculous meningitis	—	—	—
Case of tonsillitis	—	—	—
Normal blood (O)	—	—	—
Case of appendicitis	—	+ *w**	+ *w**
Case of pneumonia	—	—	—
Normal blood (S)	—	—	—

* + *w* = positive reaction weak.

From this table we see that out of eight non-typhoid cases no reaction was obtained with any of them in a 1 per cent. dilution, but in two out of four examinations a positive reaction was obtained with a 1 in 50 dilution. Taking Table V. and Table VI. together, and considering 1 per cent. dilutions only, we find that out of 16 typhoid fever cases 10 reacted to Coli III. in one or more examinations, while out of eight non-typhoid cases no positive reactions were obtained. We see, therefore, that Coli III. alone of the different varieties of bacillus coli experimented with was distinctly affected and agglutinated in many of the typhoid fever cases. In most of the cases in which a positive result was obtained it was tested with higher dilutions and the limit of positive reaction was obtained, but in only two cases was a positive result obtained with a greater than 1 per cent. dilution. These were Case 11 (Oct. 26), partial reaction 1 in 500, and Case 4 (Oct. 3rd), partial reaction 1 in 1000. Case 11 was a case of typhoid fever in a child, aged nine years, sister of Case 4. Coli III. was the stock laboratory coli culture and had been in artificial cultivation for certainly longer than a year. It was quite non-virulent and very liable to form pseudo-clumps, and frequently formed a scum on the surface, and the culture nearly always required filtering through ordinary filter paper before use To obtain broth cultures showing no pseudo-clumps special care in regard to the reaction of the broth had to be taken. In other words, it seems to have been a variety of bacillus coli which clumped very readily, and the well-recognised slight action of the special typhoid agglutinins on other bacilli, including bacillus coli communis, seems to have been sufficient in many cases to cause a positive serum reaction. Put in another way, the positive reactions obtained are due to the typhoid agglutinins and this action of Coli III. on typhoid sera does not point in any way to the formation of coli agglutinins. As already stated, many of the bacillus coli races used were obtained from patients in typhoid fever cases and in several instances were tested with the blood of the patient from which they were isolated. In no case was a positive reaction obtained. The above experiments therefore yield no evidence at all of a concurrent bacillus coli infection.

It is difficult to account for the conflicting results obtained by different observers. Some experiments of Van de Velde might be thought to throw some light on the matter. He found, after immunising two horses with two different races of streptococcus, that each serum clumped its homologous streptococcus but not the other streptococcus. The same thing might occur with different bacilli coli, and it is possible that the failure of some observers to obtain coli reactions in enteric fever cases, while success is obtained with other races, may be due to the fact that the appropriate bacillus coli races are not used Durham[17] immunised an animal against bacillus coli, and found that the immunising variety gave a positive reaction with this serum. Besides this culture one variety reacted completely, another fairly strongly, and two others gave a minimum effect, while the remaining five races were perfectly unaffected. This explanation, however, scarcely seems to be feasible, for on the same view we would expect cases of enteric fever to clump with one variety of bacillus typhosus and not with others, and this appears to be only true to a limited extent, nor does it seem to be true experimentally. Still, the differences between the members of the coli group—using the term in a narrow sense and excluding the bacillus typhosus from the group—are much more considerable than any differences between typhoid bacilli.

In regard to the possible relationship of bacillus coli to complications and to relapse, excepting Coli III. no positive reactions were obtained and no relationship is to be traced. The possible connexion with relapse has been considered above and, as Table III. shows, no reaction to bacillus coli developed after the relapse began.

The last question with which I propose to deal is whether typhoid bacilli obtained from different sources clump equally. Widal, Achard and Bensaude, Durham, and most of the earlier observers found no considerable differences between typhoid bacilli obtained from different sources. Van de Velde, on the other hand, found well-marked differences, estimating differences by time of reaction rather than by limit of degree of dilution. Lorrain Smith also found with different typhoid bacilli considerable variation in clumping power. In investigating this question the only accurate way would seem to be to determine the limits of dilution at which positive reactions are still obtained for each of the different cultures used, for, as Gruber and Durham have pointed out, sera are not entirely *specific* but rather *special* in their action, and unless the extreme limits of dilution are employed differences very possibly would not be brought out. Gruber and Durham's remarks were applied to distinct species of bacilli, but if distinct varieties of bacillus typhosus exist they would equally apply to them From the charts, and also from Table VIII., it is obvious that considerable differences exist. Excluding Ty. S and Ty. St., however, we see that the other three typhoid cultures used, though they show differences, yet they are not nearly so marked as when compared with Ty. S and Ty. St. Typhoid cultures S and St. agreed in the fact that they both very readily underwent pseudo-clumping. Sometimes sub cultures contained no pseudo-clumps, especially after filtration through ordinary filter paper, while at other times, using the same batch of broth, marked pseudo-clumps formed in less than 24 hours broth cultures Using broth cultures of varying degrees of acidity or alkalinity did not by any means always insure freedom from these pseudo-clumps. The reactions recorded in this paper could only be worked out when cultures showing no pseudo clumps were obtained. By pseudo-clumps I mean that the hanging drop preparations from the broth cultures, instead of showing the bacilli actively motile and moving all over the field, showed, indeed, many of the bacilli separate and motile, but the others were collected together in clumps, generally loose but well marked and unmistakeable and not to be distinguished from the clumps formed under the influence of the specific agglutinins. We seem to have here two distinct kinds of typhoid bacilli cultures—Ty. M, Ty. B, and Ty. R, which never, or very rarely, formed pseudo-clumps under ordinary circumstances, and Ty. St. and Ty. S, which readily formed pseudo-clumps. All these cultures have been under observation now for at least a year and no pseudo-clumps have ever been noticed in Ty. M, Ty. B, or Ty. R, even when broths of considerable differences of reaction were employed. With Ty. S and Ty St., on the contrary, it was a matter of difficulty to obtain cultures which did not contain pseudo-clumps. A scum on the surface nearly always formed and in most of the observations made this had to be removed previously by filtration. The age of the agar stock from which the broth culture was made seems to be an important factor, but here no constancy or certainty could be obtained. The Ty. S and Ty St. curves of limits of positive serum reaction cannot be compared fully with the other curves, for the different observations were not always comparable; thus, for instance, broths containing a well-marked acidity were sometimes used and factors which seem to affect the agglutinative power were in this way introduced. For this reason in considering the question of serum prognosis, but little importance has been attached to the Ty S and Ty St results when worked out. Ty. S and Ty St. were two races of bacillus typhosus which, so to speak, even when not forming pseudo-clumps yet tended to clump on slight provocation, and the degree and limit of clumping power obtained do not seem to be strictly comparable to the amount of agglutinin in the serum, but to be influenced by other (chemical and physical) factors. On the whole I have found Ty S and Ty. St. to clump to an approximately equal extent, but more considerable differences exist between Ty. B, Ty M, and Ty. R. The differences in agglutinative power shown here (and also those demonstrated by other observers) do not seem to me to be sufficient to justify the conclusion that these races represent several distinct varieties. The decidedly (as a rule) well-marked differences between the Ty. S and Ty. St. group and the Ty. B, Ty. M, and Ty. R group are more easily explained as due to accessory causes—causes which can be acquired and which may be again lost, and yielding differences altogether too variable to merit a differentiation into distinct varieties. I have, for instance, observed the agglutinative power of different typhoid races apparently to increase or decrease under cultivation. Thus when Ty. R was originally isolated, and presumably possessed a considerable degree of virulence, it did not clump at all readily and was not suitable for routine work. It was isolated in March, 1899. Its clumping power seemed to increase later and it became of use for ordinary routine work. The same remarks apply to Ty. M, but I have not noticed such differences for Ty. B or Ty. S. Ty. St. has been isolated for several years. Both Ty. S and Ty. St. appear to be quite non-virulent, five cubic centimetres at least of each inoculated intraperitoneally into guinea-pigs are without the slightest effect while Ty. B and Ty. M possessed at that time considerable virulence. The virulence of Ty. R was not tested. For most of these cultures the ability to clump varied inversely (but by no means proportionately) with the virulence, but this may have been only a coincidence. Horton-Smith[18] from another point of view arrives at the same conclusions. In support of the contention that these differences are not the differences of varieties he states that by using agar instead of broth cultures he could detect very little difference of agglutinative power. The experiments with agar instead of broth cultures which I have made are not sufficiently numerous to record, but on the whole they showed a greater uniformity than when broth cultures were used. Comparing broth and agar cultures I find, as a rule, but not invariably, that the former agglutinated more readily and at a higher dilution than the latter. This is shown in Table VII., where a few examples are given.

---

[17] Loc. cit.

TABLE VII.

Typhoid culture.	Case 6 (Oct. 31st).		Case 6 (Nov. 29th).		Case 7 (Nov. 11th).	
	Broth.	Agar.	Broth.	Agar.	Broth.	Agar.
R	+ *w**	+ *w*	—	—	+ *w*	—
B.	+ *w*	+ *w*	+ *w*	—	+ *w*	—
M.	+ *w*	—	+ *w*	—	+ *w*	—

* + *w* = positive reaction, weak. All in 1 per cent. dilution and with a two hours limit.

Summing up the matter the following conclusions seem probably justified. 1. Well-marked differences of agglutinative power undoubtedly exist between typhoid bacilli obtained from different sources, certainly when broth cultures are used, and probably also, but to a less extent, when cultures on solid media are employed. 2. That such differences cannot be considered as sufficient to justify a differentiation into distinct varieties, but are rather to be explained as due to differences of present environment and to conditions of environment which have acted in the past upon the race of bacillus, producing changes not fairly stable and permanent but liable to be again modified. In Table VIII., which gives examples of differences of reaction with different typhoid races, the *limits* of positive reaction alone are given.

TABLE VIII.

Typhoid culture.	Case 2 (Nov. 22nd)	Case 3 (Dec. 5th).	Case 3 (Dec. 12th)	Case 4 (Oct. 31st).	Case 4 (Oct. 17th).
R.	1 in 100	1 in 100	1 in 100	1 in 100	in 50
B.	1 in 100	1 in 100	1 in 500	No reaction, 1 in 100	1 in 50
M.	1 in 100	1 in 100	—	No reaction, 1 in 50	1 in 50
St	No reaction, 1 in 30†	—	—	—	—
S.	1 in 50†	1 in 1000*	1 in 1000*	1 in 500	1 in 500

* 1 in 1000 gave a well marked reaction. No higher dilutions were examined. † Of great interest in that the reactions with Ty. S and Ty. St. were less marked than with *Ty. M, Ty. B, or Ty. R* This I found to be very exceptional.

Cardiff.

ACUTE EMPHYSEMATOUS GANGRENE: A CLINICAL AND BACTERIOLOGICAL DIGEST, WITH DETAILS OF A NEW CASE.

BY EDRED M. CORNER, M.B., B.C. CANTAB., F.R.C.S. ENG.,
SURGICAL REGISTRAR TO ST. THOMAS'S HOSPITAL;
AND
H. DOUGLAS SINGER, M.B. LOND.,
LATE ASSISTANT TO THE SUPERINTENDENT OF THE CLINICAL LABORATORY, ST. THOMAS'S HOSPITAL.

IN the following paper we have thought it well first to describe a case of this disease which occurred in the practice of St. Thomas's Hospital, with full clinical and bacteriological details, as it illustrates very well one of the varieties of this disease and serves as a basis for the subsequent digest of the published literature. In writing the latter we have given first an account of the bacteriological and then of the clinical varieties, and have tried as far as possible to classify the material in a simple manner—a matter of considerable difficulty owing to the great confusion that exists with regard to nomenclature and the exact nature of the disease. Numerous synonyms have been used, such as "acute spreading traumatic gangrene," "malignant œdema," "*gangrène foudroyante*," "*gangrène gazeuse*," &c., but the title which we have given to this paper seems to give a better idea of the exact nature of the disease—viz., that of an acute specific gangrene associated with the production of gas in the tissues. It is as well to mention further that this condition is entirely distinct from so-called "hospital gangrene" and from gangrene due to causes such as injury or disease of blood-vessels, &c., belonging as it does to the specific infectious diseases such as diphtheria, tetanus, &c.

A man, aged 26 years, was admitted into St. Thomas's Hospital on March 9th, 1900, suffering from a lacerated wound of the right arm. He had been knocked down by a tram and the skin was torn from just below the elbow to a point halfway up the back of the arm. The underlying part of the triceps was also torn. The wound was immediately cleaned and sutured under an anæsthetic. Within 24 hours he complained of great pain and the temperature rose to 105·2° F. The arm was dressed, and below the elbow, over an area of the size of the palm of the hand, the skin was of a brownish red colour. The temperature fell to 102·2° at midnight but rose again on the second day to 103·4° and the pain was considerable. The discoloured part was found to be olive-green in colour and had spread half-way up the wound. The epithelium was greasy and it peeled readily; numerous bullæ were seen on the surface. Emphysematous crackling was easily felt in the tissues but no superficial veins contained air. The dead portion was separated from the living by a narrow zone of a greyish-white colour beyond which a reddish-brown discolouration extended to near the top of the wound. The smell was offensive and the patient was vomiting and looking very ill. Up to the time of Mr. F. C. Abbott's arrival the gangrene had visibly spread. We take this opportunity of thanking Mr. Abbott for giving the case to us. The arm was amputated at the surgical neck of the humerus with skin flaps, the inner being the longer as the gangrene was confined to the outer side of the arm. The muscles were cut short and the wound was scoured with 1 in 1000 perchloride of mercury and sutured. On the third day the temperature fell to 98°, but rose immediately to 103° with recurrence of pain. The flaps were found to be gangrenous, especially the inner. Amputation was performed at the shoulder joint with the smallest possible skin-flaps and the muscles were cut short; the wounds were washed well with 1 in 20 carbolic solution. The patient suffered much from shock and was infused with three pints of normal saline solution and strychnine was injected. On the fourth day the temperature fell to 99·4°, but rose again immediately to 103°. As a streptococcus had been cultivated as well as a bacillus 20 cubic centimetres of antistreptococcic serum were injected into the flank. The wound was examined and gangrene was found to have commenced in the flaps. The flaps were then excised and a large raw surface of about the size of a soup plate was left, which was scoured with 1 in 20 carbolic solution. A second injection of serum was given. On the fifth day the temperature fell to 99 4° and rose again to 101 4° Hot dressings of chlorinated soda were frequently applied The serum injections were continued On the sixth day the temperature was 100 8°. *Several small sloughs were removed from the surface, and it was noticed that bubbles of gas could be squeezed from the remnant of the pectoral muscle.* A cavity was found there and an offensive slough was removed, the smell being identical with that of the bacillus cultures The patient was much better and took food well. On the seventh day the temperature was 102 4° at midnight The wound was cleaner *On the eighth day the temperature was* 102 4° Gas bubbles were found issuing from another pit identical with the former On the ninth day the temperature was 102° A third pit was cleaned out. On the tenth day the temperature was 102° A fourth pit with two openings was found in the remains of the deltoid muscle The wound was now covered with granulations The patient was much better The pits alone were painful On the eleventh day the temperature was 100 2° Two more pits were found On the twelfth day the temperature was normal A seventh pit was found The former pits had been cleaned out with carbolic lotion, the sloughs being first removed. They never extended after this treatment On the twentieth day the pits were obliterated by granulations The wound rapidly contracted up and the patient was discharged cured on the forty-fifth day

---

[18] Loc. cit.

The following points in the history of this case are worthy of special mention —1 The dirt infection at the time of the accident 2 The extremely rapid and severe onset in a young and healthy man, the temperature rising to 105 2° within 24 hours 3 The visible spread of the gangrene within two hours 4 The rapid recurrence of the symptoms after each amputation In both cases within about 18 hours the temperature had risen to 103° or so 5 The four operations occurring within four days of his admission 6 The *formation of pits or cavities in the stump during the period* of comparative convalescence The pits were undoubtedly due to the presence and the gas producing capacity of the bacillus, which was indicated by the bubbles and the unmistakable odour But in the open wound the pits did not spread so rapidly, and when once the slough was removed, the pits swabbed, and subsequently syringed with carbolic lotion, they healed readily 7 The septic condition which was present along with the bacillus and was indicated by the bronzing and reddening of the skin, and which preceded the gangrene as it spread

Bacteriology —Cultures were taken from the subcutaneous tissue of the flap, in which gangrene had recurred after the first amputation, immediately on removal from *the body. In all the tubes inoculated a copious growth* resulted, consisting of bacilli and streptococci with well-marked gas production and a very disagreeable fœtid odour This smell was entirely absent in subcultures, but reappeared slightly on coagulated blood serum and very *markedly* in a medium containing blood Sections of the subcutaneous tissue stained with methylene blue also showed bacilli and streptococci in very large numbers The streptococcus failed to grow in subculture, so that a pure growth of the bacillus was at once obtained in the plates *The* bacilli were stout and they varied much in length, had rounded ends, were non motile, and possessed no definite capsule, though in fluid media they tended to stick together in clumps; short chains were also present No *spores* were observed. They stained well and uniformly with all the ordinary *dyes*, but not by Gram's method The organism grew best under aerobic conditions, but was a facultative anaerobe It grew well on all the usual media, best at blood heat, but also at the room temperature, cultures were alive and vigorous at the end of two months In all media, including *Uschinsky* agar, a very copious gas formation was observed, solid media being rapidly fragmented On gelatin the colonies in the depth were round or oval, yellowish white with sharp margins; on the surface white with irregular margins and a uniform fine granularity presenting *no* special characteristics There was no liquefaction The colonies steadily increased in area and thickness, reaching a diameter of from two to three *millimetres in four days* Streaked on agar, a greyish white translucent layer formed, rapidly spreading beyond the needle-track In agar stab growth occurred all along the line of puncture but more freely at the surface The medium was fragmented in from 12 to 18 hours by gas-formation In peptone *beef broth* rapid growth took place, rendering the medium turbid throughout, with a deposit at the bottom, and in two or three days a thick scum on the surface In peptone water the indol reaction was well marked at the end of 24 hours Agar containing litmus was turned blue and did not become acid in the course of 14 days Milk was coagulated in 36 hours On potato there was a thin translucent greyish growth with shining surface.

Two guinea pigs were inoculated in the peritoneal cavity with a 48 hours' culture on coagulated blood serum, both died within 18 hours In both, on section, early general peritonitis was found, in one without any exudation, in the other with a *considerable formation of lymph* Smears on cover glasses from the peritoneum showed large numbers of bacilli *apparently* in pure culture, but none could be seen in preparations of the heart blood. Cultures from the peritoneum, spleen, and heart blood in both cases yielded an unmixed growth *of* a bacillus showing the *same* characteristics as that described above with well marked gas production and fœtid odour A third guinea pig was inoculated in the subcutaneous tissue of the groin from a 48 hours' growth on coagulated blood serum In 24 hours a well marked swelling was present but without emphysema, this gradually subsided in the *course* of *four* or five days without any marked constitutional symptoms A fourth guinea pig was inoculated from a 48 hours' culture on coagulated blood serum obtained from the peritoneum of one of the first guinea pigs, also in the subcutaneous tissue of the groin In 24 hours there was a large swelling at the site of puncture with marked general feebleness, in 48 hours the swelling had increased in size, but there was no emphysema The animal was very ill, not taking food, and the eyes were bleary At the end of three days its general condition was rather better and it was beginning to take food again; it was, however, killed with chloroform On section the swelling showed simply œdema with some extravasation of blood, no gas bubbles, and no necrosis of tissue Cultures *from the swelling yielded a pure growth of the bacillus*, while those from the heart blood remained sterile Microscopically also bacilli were found in the œdematous swelling We take this opportunity of thanking Dr Louis L Jenner who kindly performed the inoculations The bacillus above described is evidently identical with the bacillus œdematis aerobius of Sanfelice, while the coccus which unfortunately failed to grow in subculture was almost certainly the streptococcus pyogenes

DIGEST OF PUBLISHED LITERATURE

Bacteriology —On looking into the literature one is struck by the small number of cases recorded with a bacteriological examination and to see how firmly the idea of its almost universal association with the bacillus œdematis maligni (*vibrion septique*) is rooted in the minds of clinicians This has undoubtedly arisen from the experimental work of Pasteur and Koch, who by inoculations with this organism first produced the condition of emphysematous gangrene; but with regard to its occurrence in man we have been able to find but very few cases in which it has been demonstrated—in fact in most of the cases published the bacteriologist has been at pains to show that the organism he found was not the bacillus œdematis maligni In some of these cases where no name is given we have taken the liberty of classing the bacillus under the group to which, from its published characters, it appears to belong Further, we have left unclassified those cases in which a bacillus was seen microscopically without successful cultivation, though in some of these the author has asserted that the organism was probably the bacillus œdematis maligni We have also tried to avoid confusion by giving each organism the name by which it is more generally known, leaving out the name of the bacteriologist with which it is often associated in the published cases—e g bacillus of Welch and Nuttall, bacillus of Welch and Flexner—a practice which is certainly confusing to anyone not possessing a special acquaintance with the subject

Bacteriologically the cases of emphysematous gangrene fall naturally into two main groups, according as the organism is (1) aerobic or (2) anaerobic These differ further in that the former probably never occur in pure culture, whereas the latter are frequently found unmixed with other organisms, and it will be found that clinically the symptoms produced differ in the two groups, the variations apparently depending on the infection or not with other, generally pyogenic, bacteria, the symptoms produced by mixed anaerobic infections approximating closely to those due to mixed aerobic ones In both groups experiments show-that the bacilli remain strictly local, spreading only by direct extension, and do not occur in the general circulation until a short time after death. This point is one of extreme importance with regard to treatment, as it indicates the possibility, by thorough local removal, of eliminating the source of the toxins which are causing the severe constitutional symptoms.

Group 1. Aerobic.—This includes the smaller number of cases, but is of special interest in that there appears to be only one micro-organism belonging to it and also on account of the close resemblance which this bears to the members of the colon bacilli group. It appears to be identical with the organism described by Sanfelice under the name "bacillus œdematis aerobius" and also independently by Klein (*ein neuer Bacillus des malignen Oedems*), who found it by the injection of garden earth into the subcutaneous tissue of guinea-pigs, where it produced emphysematous gangrene. It is interesting to note that they entirely failed to produce this disease by inoculations with cultures of the organism, for this has been the result of all attempts with cultures from cases in man where this bacillus has been isolated, although Chavigny, by using a culture of the bacillus mixed with one of the staphylococcus pyogenes aureus, produced in a dog an abscess which contained gas and caused a large slough of the superjacent skin and surrounding tissues. Muscatello and Gangitano more recently have produced gangrene and emphysema by inoculation with bacillus œdematis aerobius mixed with proteus vulgaris The uniform results with pure cultures have been the formation of an œdematous swelling without either emphysema or sloughing. The bacillus described above from the case which forms the text of this paper is identical with the micro-organism with which we are now dealing, with the exception that it was non-motile, but this is not a point of much importance, as Klein mentions that the motility in different cultures varies. In other respects the description there given will serve for an account of the bacillus of this group. It will be noticed that it very closely resembles the bacillus coli communis and is, as Sanfelice points out, probably a member of that group, differing only in minor points—viz., the excessive gas-production which takes place even in a medium not containing sugar such as Uschinsky agar, and also in the absence of the characteristic appearance of the colonies on gelatin. This resemblance has been noted by all those who have described it; Chavigny, for instance, aptly terms it "*un microbe très voisin de coli*," while he also suggests that it is identical with Sanfelice's organism. Chiari has recorded a case of the "colon bacillus" occurring in a diabetic patient, and Lindenthal and Hitschmann in Chiari's case and one of their own suggest that the gas-formation is due to the presence of sugar in the tissues, but probably the bacillus was the same as in the case which we have described above, when, as seen *in vitro*, sugars are not necessary for gas-production, and I have included their cases and those published by Bunge and Evans, who describe the organism they found as the colon bacillus, under the heading of "bacillus œdematis aerobius." The micro-organism most commonly associated with this bacillus is the streptococcus pyogenes, but the staphylococcus pyogenes aureus, proteus vulgaris, and others have been described, not uncommonly more than one being present.

Group 2. Anaerobic.—Here we have to deal not with a single organism but with at least two and possibly more, and among these must be mentioned the bacillus aerogenes capsulatus which has been found in both pure and mixed growths. We have arranged the bacilli in the order of frequency with which they have been found, and do not propose to deal at all with those which, though found experimentally in animals to produce gangrene and emphysema, have not been recorded as occurring in man.

1. Bacillus emphysematosus (Fraenkel). This bacillus has been isolated in a fair number of cases; it varies much in length, is stouter than anthrax, and occurs in short chains. It is non-motile, not capsulated, and does not form spores; it stains with the usual dyes and also by Gram's method. It grows slowly in gelatin without liquefaction or gas-formation, but freely in agar containing glycerine and sodic formate, with copious production of stinking gas. It is highly pathogenic to guinea-pigs, producing when injected subcutaneously a foul-smelling emphysematous gangrene, but is less pathogenic to rabbits, while mice are immune. It very closely resembles, and is probably identical with, as Guillemot has pointed out, the bacillus described by Veillon and Zuber under the name of "bacillus perfringens" which was found by them in the pus of many cases of appendicular abscess. This is a point of interest, showing that the bacillus occurs in the intestinal contents, and it may serve to explain some of those cases arising from injury without breach of surface. In this group we have included three cases by Wicklein who, however, did not give a name to the bacillus which he found.

2. Bacillus œdematis maligni (*vibrion septique*). The only recorded instances in which this organism has been isolated are the cases published by Chauveau and Arloing from an outbreak of emphysematous gangrene in the wards of the Hôtel Dieu, Paris, and one can have no doubt after reading their papers that they conclusively proved that the gangrene was due to this organism. Charrin also showed sections of tissues containing the bacillus from a donkey inoculated by Arloing. It is certainly curious that we have been able to find no other cases in which the organism has been cultivated, in spite of the general belief in its frequency, as shown by the fact that in Flügge's text-book on bacteriology it is stated that a whole series of cases in man has been published. Rosenbach in his work entitled "Mikroorganismen bei den Wund-infektions-Krankheiten des Menschen" records two cases in which he found microscopically a sporing bacillus which he believed to be bacillus œdematis maligni but which he failed to cultivate. Slater, Bremer, and Menereul also say that they saw a bacillus which was probably the bacillus œdematis maligni but they failed to cultivate it and they give no reason for their assertion. The bacillus occurs singly or in chains, is of varying length, and is somewhat narrower than anthrax. It forms spores generally in or near the middle. Its motility varies. It stains readily with the ordinary dyes and also by Gram's method. Copious gas-formation occurs in all media and gelatin is slowly liquefied. It is highly pathogenic to most animals, including guinea-pigs, rabbits, and mice.

3. Bacillus aerogenes capsulatus (Welch and Nuttall). This organism has been described in four cases, one by Mann and three by Muscatello and Gangitano. The latter authors have performed a series of very valuable experiments with the organism which they found, and they show that this bacillus, although non-pathogenic to undamaged tissues, produces gangrene with emphysema when the tissues are first rendered less resistant either by mechanical damage or by the injection of bacterial toxins. But unfortunately, they assert, as does Mann, the identity of this bacillus with the bacillus emphysematosus of Fraenkel, whereas this latter produces emphysematous gangrene when injected alone into healthy tissues in guinea-pigs, and, further, is non-capsulated. Partly for this reason, but mainly because the cases differ in important points clinically, as the authors themselves point out, from the disease which we have described above, we have thought it advisable to put these under a separate heading, both in the clinical account and in the bibliography.

Clinical.—Considerable difficulty was experienced in dealing with the cases recorded owing to the insufficient data, both bacteriological and clinical, given. The difficulties ran chiefly along these lines, which may be briefly indicated. It is very rare that the condition of the arteries is recorded and not infrequently the age is not stated. This is an important point, for the gangrene excites inflammation in the neighbouring living tissues and if the arteries cannot supply them with the extra blood demanded the gangrene becomes spreading in character. Should the tissues be otherwise below par so much the more rapid is the spread of the gangrene. The second point is that it is frequently impossible to decide whether the emphysema is due to a specific organism or due to the ordinary decomposition of dead tissues. The time of its occurrence is frequently not noted. The third point is the occurrence of anomalous cases, such as are well attested by Chavigny and Seydel.

The following is a brief outline of the lines upon which the clinical matter has been found to plan out and it is very interesting in its agreement with the bacteriology. First have been considered cases due to mixed infection; secondly, those due to pure infection; thirdly, a few remarks are given as to treatment; fourthly, some anomalous cases are described; and finally are appended a series of cases due probably to the bacillus aerogenes capsulatus.

Cases due to mixed infection.—These cases may result from the action of an aerobic organism, the bacillus œdematis aerobius, or from an anaerobic bacillus combined with pyogenic organisms. The case that forms the text of this paper illustrates clinically those due to mixed infection excellently. Signs of both inflammation and of specific gangrene are present, the former process probably acting as a forerunner to the latter and rendering the tissues an easier prey to the bacillus. The onset occurs within 24 hours and is ushered in by great pain, a high temperature, a rapid pulse, and sometimes a rigor, and is soon followed by vomiting. The region affected is at first red, swollen, and acutely tender. Gas-formation in the tissues is noted early and the gangrene spreads rapidly. A bronze discolouration is seen round the gangrenous patch and precedes the gangrene as it spreads In this area there is no gas-formation and the tissues do not crepitate. The spread of the gangrene may be seen in two hours and is sometimes much quicker than this. If untreated the patient usually dies on the third or the fourth day from septic intoxication. The smell of the gangrene is frequently very foul or it may resemble that of rancid butter. This form of gaseous gangrene is naturally the commonest, from the mode of infection—by earth, dirty wounds, compound fractures, &c. Some have assumed that the bacillus coli communis is the cause of gaseous gangrene in diabetes and that the presence of this latter disease is necessary for the bacillus to produce the former. From the description of the organism by Lindenthal and Hitschmann it is most probably the bacillus œdematis aerobius which produces gas in all media and the presence of carbohydrates is unnecessary. To this variety of gangrene the name of "coli-gangrene" has been given. But it is most probable that these cases are examples of that which has been described above and with which they agree clinically.

In connexion with diabetes it may be well to refer to some difficulties that may arise. In these cases the arteries are diseased and therefore cannot respond to the extra call for blood demanded to form the inflammatory line of demarcation. The tissue at that point dies and the gangrene becomes spreading in character, which is further increased by the bad trophic condition of the tissues, which are themselves below par and owing to the sugar afford excellent pabulum for the growth of organisms. It is, in consequence of the last consideration, easy to see that decomposition will be very rapid and that the gangrene may present the appearance, locally at least, of the acute emphysematous variety. This similarity is further increased by the presence of the bacillus coli communis and its relatives amongst other organisms, which have been described as producing specific gangrene.

Cases of mixed infection with anaerobes are apparently less common and only one clinical description could be found—viz., by Guillemot—which does not differ from the above. Other cases are mentioned by Fraenkel, Lindenthal and Hitschmann.

Cases due to pure infection.—Cases of pure infection are invariably due to an anaerobic bacillus and have not infrequently been recorded, but unfortunately full clinical details of the individual cases are not given. The onset, as in the inflammatory variety, appears usually within 24 hours of the accident. One of the earliest symptoms is great pain in the part affected, accompanied by swelling and gas-formation. The signs of inflammation and suppuration are entirely absent and the part is usually pale, swollen, and emphysematous, with the blue veins standing out like the veins in a piece of marble. The part is very painful, but later it becomes anæsthetic The circulation in the veins becomes stopped and not till then can bubbles of gas be seen in them. If the part is still left it rapidly becomes offensive and undergoes decomposition The spread of the gangrene is extremely rapid and has been variously estimated by authors, as has that of the mixed infection, from one-half to two inches per hour. The rate of spread of the pure infection is naturally not nearly so easily estimated as of the mixed infection Constitutionally the patient shows signs of a profound toxæmia. The temperature is sometimes slightly raised to 100°, but more frequently it is about normal and not infrequently it is subnormal. The pulse becomes progressively more and more rapid and small, but occasionally it may be quite slow or normal in rate. The mental condition also may differ from that of the mixed infection in that the patient seems to be less frequently delirious and in some cases is quite clear in his mind until near the end, which, as in the former type, is usually ushered in by delirium, vomiting, and diarrhœa Even in the extensive literature that it has been our lot to consult we have been unable to find recorded, with full clinical details and a reliable bacteriological examination, a case of pure infection. The above description is mainly based upon that of Lindenthal and Hitschmann who had the good fortune to study four cases of pure infection.

The above description of cases of pure infection is founded upon those due to the bacillus emphysematosus. Recorded cases due to the bacillus œdematis maligni are rarer. Rosenbach has described two doubtful cases. Chauveau and Arloing have described some cases, but they show no marked differences from those due to the bacillus emphysematosus.

Treatment—With regard to treatment little can be said except that early amputation should be performed, and this is further emphasised by the strictly local infection. One word of warning may be given from the case reported in this paper. Lindenthal and Hitschmann say that the infection goes on chiefly along the lymphatics and therefore a mistake was made in using a larger internal flap in the first amputation in our case. Cases have been cited at different times of amputation through emphysematous tissues. It seems doubtful if such an operation could result in the patient's recovery. And where such a result is recorded one is inclined to regard the case as one of putrefactive emphysematous gangrene and not specific On the other hand, quite a number of cases have been recorded in which gangrene has recurred in the amputation stump and has been followed by recovery. Guillemot's case may be cited, as also may that of Tubby and Wright and the case in this paper. The amputation removes a very large amount of the manufactory of toxin and allows the patient to recover, as is shown by the immediate improvement. Amputation through the bronzed part beyond the gangrene may be good practice, though suppuration, as the bronzing is produced by the septic organisms in mixed infections, is sure to happen. This was the case with that dealt with by Tubby and Wright and also in our case. In the cutting away of the flaps at the fourth operation in our case bronze staining was left on the neck and quickly disappeared. Anti-streptococcic serum may be injected possibly with advantage in some cases, especially if the presence of a streptococcus has been proved. These organisms may fulfil the rôle of forerunners and injure the tissues, thus rendering them an easier prey to the specific bacillus. The point may certainly be raised as to the need for the performance of a second amputation for recurrence of gangrene in the stump. A few cases have been recorded of recovery following renewal of the gangrene, but many patients have died from the recurrence. Therefore it may be urged upon general lines that secondary amputation may be performed when the situation of the recurrence allows, and failing this, incisions, drainage, and disinfection. Large and hot dressings of some disinfectant like chlorinated soda are also valuable The treatment for the peculiar pittings which were noticed in the case here described has been mentioned in the account already given.

One paper has been written upon the serumtherapy by Leclainche. He deals entirely with the subject from a veterinary point of view and with the serum derived from cases immunised with cultures of the bacillus œdematis maligni. As this bacillus is rarely found in the emphysematous gangrene of man the paper is of little practical value to us. The veterinary text books are very silent upon the subject of gaseous gangrene and this is to be expected as it has been found experimentally that many animals are refractory to inoculation experiments

Anomalous and subacute cases.—Besides the above examples of pure and mixed infection and the various clinical types of an acute gangrene a number of cases exist in which the clinical characteristics are different. Chavigny has suggested from a study of his case that these were cases of subacute gaseous gangrene and also that they arose from auto infection through the blood and probably from the bowel There must be a quantity of records of such cases, but owing to the lack of the important details it has been impossible to include them in the bibliography. The usual difficulty is to decide whether the emphysema is the result of ordinary putrefactive changes or whether it is due to a specific gangrene. Examples of such cases are well worth reproducing.

A male, aged 21 years was thrown from a horse on April 24th, 1896, and sustained a comminuted fracture of his left femur and fracture of his left tibia and fibula; neither injury was compound There was no pulse in the anterior or the posterior tibial arteries On the second day the limb became warmer and the pulsations of the arteries were noticed after 48 hours from the accident. The limb progressed most favourably save for some loss of sensation. On the fifth day the patient had some slight rise of temperature, but it was not until the twelfth day that gangrene appeared on the foot and was heralded by rise of temperature and the usual constitutional symptoms; locally it was characterised by early gas-formation and was both rapid and spreading. Amputation was performed through the knee-joint on the fourteenth day—i.e., within 48 hours of the onset of the gangrene. Three days later suppuration and gangrene recurred in the stump and the patient became jaundiced one day later—viz., on the eighteenth day. There was little or no fever throughout the illness, the appetite was good, and the mental condition was clear and active until the death of the patient, which occurred on the twenty-fourth day after the appearance of the gangrene. Bacteriologically an aerobic bacillus was found in pure culture.[1] Chavigny points out that throughout the course of this case the symptoms were all subacute as compared with those of *gangrène gazeuse foudroyante*. But a bacillus was isolated which agreed on all points with some of those obtained from the clinically acute cases. He also found experimentally that the virulence of the bacillus was increased if septic organisms were injected with it. He says that this subacute form is different in its causation and symptoms from the ordinary acute cases, and is produced by auto-infection probably from the bowel. Seydel,[2] describes a somewhat similar case but which was more subacute than Chavigny's. A man received an injury without wound to his foot. Gangrene did not appear until the thirteenth day and did not spread rapidly, so that amputation was not performed until the twenty-fifth day Death occurred on the thirtieth day. Bacteriologically immense numbers of streptococci and staphylococci were found, but he failed to obtain any other organism. As he makes a special point of the very early appearance of emphysema in the tissues there must have been some specific gas-producing organism present. The gas was present in large quantities. Milliard and Manley may be mentioned amongst a large number who record somewhat similar cases, but owing to the lack of full bacteriological and clinical data little can be made of them. It is interesting to note that no subacute case of pure infection has been recorded.

Cases probably due to the bacillus aerogenes capsulatus.—There is still another set of cases anomalous clinically and of which the bacteriology is not quite definite. These cases are reported as being due to the bacillus aerogenes capsulatus. Muscatello and Gangitano have published two cases of pure infection and one of mixed infection, as has also Mann. These cases are briefly reproduced.

Pure Infection.

CASE 1.—A healthy man had his popliteal artery tied and an aneurysm excised. The gangrene appeared within 36 hours. The temperature rose to 105 4° F. and emphysema was noted. On the second day after the gangrene appeared the leg was amputated through the thigh which was followed by recurrence of gangrene next day. The wound was opened up and disinfected, the man recovering.

CASE 2.—A woman, aged 45 years, underwent nephrectomy through the loin. On the fifth day the temperature rose to 100 4° F., on the sixth day to 101·4°, on the eighth day to 103 8°, and she had a rigor. Free incision, lavage, and drainage were done, after which the temperature at once rose to 106°, but she recovered.

The characteristics of this gangrene with pure infection are given as follows: (1) early emphysema and toxæmia; (2) absence of inflammation; and (3) very little tendency to spread. It differs from the cases of pure infection already described in that the latter show (1) great and rapid spreading; (2) apyrexia in contradistinction to temperatures of 105·2° and 106° F.; and (3) that the gangrene does not yield easily to incisions and drainage, thus being of infinitely worse prognosis. On the other hand, they agree in the early and great emphysema and the absence of signs of inflammation.

Mixed Infection.

Muscatello and Gangitano have published one case.

CASE 1.—A man, aged 30 years, sustained a fracture of the os calcis and hæmatoma of the dorsum of the foot, which was incised. Within 24 hours there were swelling and inflammation of the foot and high fever. During the next three days the gangrene, which was emphysematous, spread nearly to the knee and on the fifth day the knee crepitated. On the sixth day amputation was performed through the thigh. 36 hours after the operation there was recurrence in the stump with fever and inflammation. The wound was thoroughly disinfected and the patient recovered. In the amputated limb were found streptococci, staphylococci, and the bacillus aerogenes capsulatus. The authors class this case with their others due to mixed infection with streptococci and anaerobic bacillus.

Mann in the "Annals of Surgery" also records a case.

CASE 2.—A man, aged 47 years, had a blister on his hand for one week and then it began to swell, accompanied by an acute onset and a rigor. On the first day incisions were made and improvement followed; the temperature was 102° F. On the second day the temperature was 99 2°; the hand became very painful on the third day. On the fourth day the patient had two rigors with a temperature of 105·5°. Extensive incisions were made and the limb was placed in a hot bath of perchloride of mercury. Six hours later the temperature fell to 104°; nine hours later it was 103°. On the fifth day the temperature was 102°. In three days' time the sloughs separated and the wounds slowly healed. A bacteriological examination yielded cultures of streptococci and the bacillus aerogenes capsulatus.

These cases of mixed infection with the bacillus aerogenes capsulatus differ from those of pure infection in that they are more spreading in character. In fact, the cases of mixed infection approximate more closely to those due to mixed infection above described than do the corresponding ones due to pure infection. In both cases the gangrene recurred in the stump and yielded to disinfection, recalling the similar result in those due to pure infection of the bacillus aerogenes capsulatus. The influence of the septic organisms is shown by their causing the mixed infection to be the more spreading in that the tissues are first injured. This emphasises the point already made, though it is doubtful if the presence of septic organisms renders the mixed infections previously described more rapid than the pure infections. In both varieties of cases, the pure and the mixed, the gangrene due to the bacillus aerogenes capsulatus is of an infinitely better prognosis than is that due to the organism just described.

FIBROID TUMOUR AS A COMPLICATION OF PREGNANCY AND LABOUR.

BY JOHN E. GEMMELL, M.B., C.M. EDIN.,
HONORARY SURGEON TO THE HOSPITAL FOR WOMEN, LIVERPOOL, HONORARY MEDICAL OFFICER TO THE LYING-IN HOSPITAL, LIVERPOOL.

THE following two cases of the complication fibroid tumour and pregnancy which have been under my care during the last year I have thought of sufficient interest to record, from the diversity of the symptoms produced and the line of treatment necessitated.

The site of the tumour was about the same in each case, yet in the first case there was nothing during utero-gestation to lead up to the diagnosis of its presence, the symptoms appearing with the onset of labour, associated with eclampsia, sapræmia and septic peritonitis following, both attributable to the presence of the tumour. In the second case the tumour produced its symptoms early (at the third month), necessitating abdominal section and enucleation of the tumour, and it is remarkable from the fact that, notwithstanding active manipulation of the uterus at the time of operation, the pregnancy went to term and a full-time child was born.

CASE 1. *Labour complicated by puerperal eclampsia; fibroid tumour; sapræmia; septic peritonitis; abdominal hysterectomy; recovery.*—A woman, aged 38 years, a primipara, was admitted to the Lying in Hospital, Liverpool, on Nov. 30th, 1899, being sent by Mr. W. R. Main of Heswall, with the history that the patient was at about the full period of utero-gestation, and had been seized with convulsions on Nov. 29th and that there was a tumour in the abdomen. The patient had travelled from Heswall (10 miles) in an ambulance carriage, and when admitted was only partially conscious, could not be roused to answer questions, was restless, especially when touched, and occasionally moaned as if in pain. Abdominal examination presented a full-time uterus in which occasional contractions were felt. In the right iliac fossa, close up to the uterus, reaching a point on the level of the umbilicus and seeming to pass down into the pelvis, was a hard tumour which appeared to be fixed to the right side, and was dull on percussion except at its upper border, where the note was resonant. Per vaginam the cervix was felt high up and admitted the tip of the forefinger. No urine had been passed, but there were no fits. The diagnosis was that of a renal or an ovarian cyst complicating the labour, and as her condition seemed better than when Mr. Main had last seen her she was given 30 grains of chloral and bromide with 10 minims of tincture of digitalis every four hours. On Dec. 1st she had had a fairly good night; she had had no fits and had passed 14 ounces of urine, the specific gravity of which was 1015, acid, one-third albumin, and no blood or casts When seen at 9 45 A.M. she was lying on the left side, unconscious; she was breathing heavily; the face was cyanosed, conjunctival reflex was present, the pulse was 148, and the temperature was 98·6° F. Per vaginam the cervix was now obliterated, the os was high up and far back, dilated so far as to admit the finger, and was rapidly dilated so as to admit the whole hand. The presenting part was the vertex, or rather a portion of it represented by the scalp, with a parietal bone; no sutures or fontanelles could be distinguished but a wide membranous space on either side of the parietal bone; a second parietal was felt posteriorly and to the left side; an ear was felt high up on the right side of the pelvis. There was no bulging of the abdominal wall above the symphysis pubis, and the diagnosis was that of a "dead fœtus." The labour was allowed to progress unaided until 4 45 P.M. when, there being no advance since morning except that the soft vertex had been pushed through the os like a bag of membranes, forceps were applied above the brim and delivery was easy; there was delay with the shoulders and the third stage (no hæmorrhage and no uterine contraction), in consequence of which the hand was introduced into the uterus, where the placenta was found lying, already detached, and was removed. The uterus was douched with iodine water (four minims to the pint). The pulse was 108. The patient was more conscious. On Dec 4th, the lochia being offensive, a vaginal douche of permanganate of potash was given three times. The temperature was 101° on the next day, the 5th. As her condition gave rise to some anxiety the uterus was douched and curetted, offensive blood-clot being removed, and the uterus was packed with double cyanide gauze. The position of the tumour was now in the middle line of the abdomen and was freely moveable; it was of a soft solid consistence and could not be felt from the vagina, so that diagnosis of a dermoid ovarian tumour with a long pedicle was made. On the 6th the patient was better. The temperature was 99·4°, and her pulse was 118, but there was marked tenderness over the left side of the abdomen. On the 8th, during the night, the patient had a rigor and the temperature went up to 104·2°, and the pulse to 140. At 10 A.M. the pulse was small, 132, and the temperature was 102·4°. The abdomen was much distended, tympanitic, and tender, especially over the tumour. The patient was obviously suffering from septic peritonitis, which was thought probably to be associated with a twisted pedicle; if left alone she would certainly die, and her only chance was abdominal section. My colleague Dr. A. J. Wallace, being in the hospital at the time saw her with me and agreed with this opinion, whereupon we arranged for operation the same afternoon (the 8th).

The abdomen was opened by the usual median incision and on opening the peritoneum offensive blood-stained serum escaped. Passing the hand into the abdomen the tumour was found to be a fibroid attached to the fundus of the uterus by a broad pedicle, and was lying retroverted in the pelvis, where it was adherent by recent peritonitis and was with difficulty separated from the intestines and the floor of the pelvis. The incision was prolonged up to the umbilicus to enable the tumour to be withdrawn, and in delivery of the growth a small slough was found where the tumour was bent upon the uterus, and during manipulation my finger passed into the wall of the uterus at this point. There were several smaller fibroids in the walls of the uterus, and feeling that the operation should last as short a time as possible hysterectomy was preferred to myomectomy as presenting the best chance for the patient. Baer's operation was performed, the stump of the cervix was covered in with peritoneum, and the broad ligaments were sutured. An opening was made through the pouch of Douglas into the vagina, and gauze was packed from the peritoneal cavity to the vagina, and further drainage was provided for by a glass tube from the lower angle of the abdominal incision. The peritoneal cavity was thoroughly cleansed with saline solution and the wound was sutured with silkworm gut and dressed with double cyanide gauze. On Dec. 9th the patient slept for two and three-quarter hours during the night She complained of severe abdominal pain; the abdomen was swollen and tender, but the temperature was normal and the pulse was 128. The tongue was dry. On the 10th the dressing was changed; two drachms of sero-purulent offensive fluid were removed through the drainage-tube. On the 12th the dressing smelt offensively; it was removed and a sero purulent discharge oozing from the abdominal incision was found The sutures were removed and the whole line of incision was one large putrid slough going down to the muscle. This was brushed over with pure carbolic acid, and leaving the wound gaping bran and borax poultices were applied In three days (the 15th) the wound cleaned up, and there was a free drain through to the vagina. From this she rapidly improved and left the hospital quite well on Jan 5th, 1900.

One point in the convalescence is of value. A few days after the operation, finding the pulse remaining quick and small and feeble, 10 minims of tincture of digitalis were given every four hours and continued; one morning, however, the temperature fell to 97° and the pulse rose to 160, and was intermittent and barely perceptible. Her skin was moist and her appearance was dusky; there was vomiting of bilious fluid. The tongue was dry and brown. Food had been pushed, so that the attack looked like either an acute septic absorption or stomach derangement, and it was felt that probably the digitalis was upsetting her. The digitalis was discontinued and a dose of calomel was given and the patient starved for 24 hours and rapidly improved.

The points which I wish to bring under notice are, firstly, diagnosis. From the position of the tumour on the right side and in the lumbar and iliac regions, from its apparently being fixed, and that the bowel note was found in front of it, it seemed to present the features of a renal tumour. Mr. Main, however, had stated that he had moved the tumour and had pushed it out of the pelvis, therefore I judged it was a tumour with a long pedicle and possibly ovarian. Then after delivery the great mobility of the tumour and its soft solid feel gave me the impression of its being a dermoid from vaccine lymph. The yellow organism showed tetrads, and these tetrads are to be seen in the preparation, but unfortunately it is mixed with the white. The preparation was made from a white and yellow colony, or from the yellow colony, but it shows white and yellow. The third preparation is one of opaque lymph and you will see that there are colonies of organisms in it. I am sorry that I cannot show you a preparation of clear vaccine lymph. It is a most difficult thing to show and in the time at my disposal I was not able to search out what I wanted, so I can only describe the difference between opaque lymph and the clear standard vaccine lymph. In clear standard vaccine lymph you see very few organisms, or next to none. These organisms are isolated. They are very minute and they measure about the $\frac{1}{24000}$th part of an inch in diameter. The organisms of the cultivations under the microscope are 0·1 to 0·3 of a micro-millimetre according to the mode of preparation. If you roll them too much you may see the larger forms of cocci. The units of the tetrads, for instance, may vary from the tenth of a micro-millimetre to one micro-millimetre in diameter. I attribute that to defect in preparation.

The question came to be, what did all this mean? I began to look on all these different cultivations, opaque lymph, variolous lymph, and clear vaccine lymph, as different materials. All these materials were of different composition, and it was evident that the natural material had a different physiological action from the cultivated material. In trying to explain this I was confronted with the classification of bacteria. At that time bacteria were only beginning to be studied exactly and the battle raged fiercely between iso-morphism and pleo-morphism. A distinct bacterial form, according to Koch, corresponds to each infective disease, and this must be shown before it is proved that this bacterial form is the cause of the disease. At the same time he admits that the pathogenic forms which give rise to scarlet fever, variola, and vaccinia are so minute as to be difficult to recognise owing to their minuteness, and he advocates cultivations in the animal body so as to be able to show their infectivity.

Now, with these views before me—that all organisms were either spherical, rod-shaped, spirillum, or something of that kind, and that one could not pass into another; that if you said the cocci became bacilli you were a heretic; and that the thing must not grow but must always be the same—it seemed to me that there was a want of logic about the whole thing, and I rather went perhaps beyond the mark in attacking the classification of bacteria to suit my own views. I could not but see that these preparations showed different sizes of organisms. I did not know why, but there was no doubt that they did show different sizes of organisms. Then again, although they grew, it did not follow that they changed their species, and growth seemed to be a natural condition of all organisms which had life, and when they were so minute we had, as it were, to take into account their growth forms as well as the exact bacterial form which was displayed at the time that I observed them. Now the bacterial form in this clear lymph appeared to be a very minute spore. I assumed that owing to the behaviour of lymph on drying it could not be a vegetative condition of organism; that the material, whatever it was, had very strong resistant power to destruction. So, first in a communication to the Royal Society of Edinburgh, and again in a book which I published 14 years ago, I advocated the view that the organism in vaccine lymph was a spore. I also advocated, I must say more than I should have done, pleo-morphism, not the mutability of species, but the possibility of growth forms of cocci. I still hold these views, because I am not able to distinguish these from minute organisms which, say, may be produced by yeast. Pasteur showed that yeast adhered to the skin of grapes, but that as long as the grape skin was sound it took no effect. When there was a crack in the skin, however, the yeast attacked the grape and fermentation took place. I do not know the size of the grape spores, but it seems to me that between the vegetative condition of an organism and the reproductive condition of the organism there might be not only a difference of size but also a difference of action. Acting on this idea I formulated a sort of scale of growth for cocci from the minute spore of the cocci to a large form seen in lymph. If I had known as much about bacilli as I do to-day I might have said that these were spores of bacilli which we found in lymph. As a matter of fact I did say in criticising Zopf's classification that he had named three of his classes as cocci, and if one of these grew to be bacilli, they ought to be called spores of bacilli. So we come to this conclusion—that the organisms of the lymph are spores. Where, I think, I went wrong at that time was in thinking that these spores could grow in their own exhausted nutrient material. Since my observations have been published the whole subject has been thoroughly thrashed out, and it has been shown by Dr. Klein and Dr. Copeman that these white, yellow, and orange organisms are saprophytic, that they have nothing to do with the vaccine organism, and that they are extraneous organisms and are contaminations.

Now these views quite fit in with my own work. I am prepared to find that these are saprophytic organisms. What I maintained 14 years ago was, that the active principle in the lymph consisted of spores, that these cultivated spores, even if they were developments of the spores of lymph, were incapable of producing vaccinia, but at the same time that they were the cause of opacity in lymph. It is now a well-established fact that the cause of opacity in lymph is a natural cultivation of the organisms in it. I thought at the time that the spores in the lymph might develop. Since I have looked more carefully at the matter in the light of recent observations I think you cannot look for development of spores in the lymph, that there must be contamination to account for opacity, because the spores are the resting-stage of the organism, the stage at which they can reproduce themselves, and they have exhausted their pabulum by the time they appear in the vesicle, so that we cannot expect them to grow into cocci or bacilli or anything else.

Simultaneously with my own observations, Dr. Neil Carmichael of Glasgow found cocci in lymph. He considered that they were the active principle. He was able to inoculate them in 10 per cent. of the cases of children whom he had vaccinated. He did not consider that failure in 90 per cent. of the cases was sufficient to cause it to be disputed that cocci were the active principle in vaccine lymph, but that cultivation diminished their infectivity. We are possibly both wrong, but it is a remarkable fact that both Voigt and Garré have also failed to cultivate these organisms. Voigt believed that he had cultivated the vaccine organisms and could reproduce vaccinia in the calf, but he found as his generations departed from the original cultures that they diminished in potency. Garré, on the other hand, was able to inoculate calves with his cultivations, and from calves he could vaccinate children, but when his cultivations were inoculated into the human subject directly he failed.

Since the observations which I have detailed Dr. Klein and Dr. Monckton Copeman have made further observations. They have cultivated lymph in all sorts of ways and Dr. Copeman has shown that these organisms in my reports are extraneous organisms. So far as I know, they have not got any nearer the cultivation of the vaccine organism, but I am glad to see from recent papers that they corroborate my view that the active principle in an active vaccine material is a spore. They account for there being no other organism in the lymph by the fact that the organisms that produce them have probably given way to spores before they appear in the lymph, and they describe the spore-bearing bacilli which produce these spores. It is almost an induction that if you have spores there bacilli may be the cause of them, more especially as "micrococci do not produce spores" (Klein). At the same time their attempts at propagating the spores, either in the human or in the animal subject, have entirely failed. Dr. Copeman thought that he had got cultivations of his bacilli from egg and Dr. Klein has used glycerine agar and solid serum and so on for cultivating his organisms, but so far without success. The subject is one of difficulty and complexity and one can only hope to be able to put a stone in the building, which I have no doubt will be completed at some future time, by the successful cultivation of these vaccine organisms.

ACTION-AT-LAW AGAINST A MEDICAL MAN.—At the Pontypridd County Court on Nov. 7th, before Judge G. Williams, an ex-steward of the Ferndale Constitutional Club sued Dr. J. Williams for an alleged slander. The alleged slander was that Dr. Williams on April 9th had accused the man of disobedience, drunkenness, and dishonesty. The judge held that the defendant was perfectly justified in the words which he had spoken and gave judgment for him with costs.

REMARKS ON TWO CASES OF LANDRY'S PALSY.

BY T. WARDROP GRIFFITH, M.D. ABERD.,
SENIOR ASSISTANT PHYSICIAN TO THE GENERAL INFIRMARY, LEEDS.

SINCE the attention of the medical profession was first directed by Landry in 1859 to the form of paralysis which bears his name, and the description of which was based on 10 cases, many instances more or less similar have been put on record from time to time. Authorities differ among themselves greatly as to the criteria which should determine the admission of any given case to the category of "Landry's disease" Some limit the term to a rapidly ascending form of palsy with no affection of sensation or with very slight sensory phenomena only; some admit the possibility of marked anæsthesia; while others would exclude cases with obvious changes in the spinal cord and peripheral nerves on the ground that instances exist apparently without either. From this it is clear that a more extensive pathological study of the disease may show that the term "Landry's paralysis" includes several conditions which may be related to one another but are not identical, and, like all such terms, it must be used provisionally and clinically and not as corresponding to a definite pathological equivalent.

With this preface I shall therefore narrate two cases which in my opinion are examples of the disease, and then make a few remarks on the reasons which have led me so to classify them, as in some respects they do not fit with the concise description met with in certain of the text-books.

CASE 1.—The patient was a man, aged 40 years, whom I saw in consultation with Mr G. B. Hillman of Castleford in June, 1899. This man had always had a tendency to "throw on" his club, upon small provocation, so that when some 10 days before, he complained of pains in his legs, followed on the next day by some indefinite pains in his back; *there was nothing in his condition to sound a note of* alarm, and it is possible, as Mr. Hillman suggested, that the march of the earliest symptoms may have escaped accurate observation. The day before I saw him, however, his legs were decidedly weak, and some hours before our consultation Mr. Hillman observed partial right sided facial palsy. We examined the patient together He was not looking very ill and was not suffering. He had almost complete motor palsy of his legs; when he tried to move his feet or his toes the effort was immense and the result was almost *nil.* The muscles of the trunk were weak and, although the intercostal muscles acted all the way down and the diaphragm also acted, yet the respiration was *mainly of the superior costal type. The patient's hands* were very feeble, especially the right hand, and there was general weakness of the arm and forearm, the movement of extension of the forearm being especially affected. The shoulder muscles were strong and the power of shrugging the shoulders was well up to the normal standard. The sterno-mastoids, especially the right, were weak. Thus the patient could not raise his head from the pillow and rotation of the head was *lessened in extent, speed, and strength.* There were slight dysphagia and some weakness and alteration in the voice, but no palsy of the palate. There was partial facial palsy of Bell's type on the right side, with some weakness of the right external rectus and consequent homonymous diplopia, which was constant The deep reflexes were all abolished. There was marked anæsthesia affecting the whole of the lower extremities and the extreme lowest part of the abdomen, with very questionable affection of sensation in the arms and hands. The patient had to wait some time before succeeding in passing water, but there was no actual retention or incontinence. The pupils were equal and active There were no trophic lesions or vaso-motor disturbances An indefinite history of exposure to cold was made out We gave a hopeless prognosis, which was justified, for the patient died on the following afternoon In a letter to me Mr. Hillman wrote: "I saw him again the same evening The paralysis of the right external rectus was much more marked than when you saw him, the throat was much more affected, and there was a good *deal of difficulty in swallowing*, while the chest movements were almost confined to the upper ribs. Next morning there was no movement of the lower ribs or of the abdomen Speech was almost gone. There was slight deflection of the tongue to the right on protrusion. He had passed urine into the bed during the night, but it appears he had tried to explain his want and his friends did not understand him. He was quite unable to swallow. At two o'clock in the afternoon he remained quite conscious but could not speak; the palsy of the external rectus was now complete, the face and hands were becoming cyanosed and he was obviously dying. At 3.40 he became markedly cyanosed and he died about four o'clock with slight spasm of the face."

In this case the salient features were the premonitory pains, the rapidly developing palsy, more or less, but not *strictly* ascending in character, with some affection of the cranial nerves, loss of reflexes without marked affection of the sphincters, and decided anæsthesia of a more limited distribution than that of the motor palsy, the whole terminating in respiratory palsy in about 11 days.

CASE 2.—I was associated in this case with Mr. A. Smith of Stanningley. The patient, a woman, aged 24 years, was admitted under my care into the Leeds General Infirmary on July 1st, 1900. She was the youngest of a family in whose history no special diathesis could be made out. She herself had had chorea on three occasions about 11, 13, and 15 years previously and she had had influenza some time in 1898 She had been robust and muscular. She had been confined of her first child three years before and this was followed by a miscarriage 12 months after, and this again by a living child in August, 1898. The labour was normal and she did well *for 10 days. Then the temperature went up to 103° F.* and remained high for four days, and she made a *slow recovery and never looked herself again. Four* months after her confinement she said that her work was a burden to her, and her child was weaned. She dated her illness from about one month prior to her admission into the infirmary, when she noticed that the palm of her left hand was numb The numbness spread up the arm and at the end of a fortnight it had reached the left side of the neck and the head. Here it stayed for a few days and then began to descend the left side until it reached the groin. Thence, after a short delay, it advanced further down the limb, which in turn became numb in its whole extent. Her *condition at the time was well described in a letter from* Mr Smith, who wrote: "The anæsthesia for both heat and pain was very well marked over the whole of the arm and forearm, less marked on the inside, and still less on the left leg; the right side was quite normal. The muscular sense as tested by weights was normal on the right side, distinctly impaired on the left." In about 48 hours numbness began on the right side, first in the hand extending up to the elbow, then in the right leg, which was affected at first on its inner and anterior aspect, the numbness then extending down to the toes. All these sensory phenomena came on before the motor affection, which was gradual in onset, and it was by no means clear whether the arms or the legs were the first to be *affected. On admission into the infirmary she expressed herself* as feeling quite well so far as her general health was concerned. There was great motor weakness; she could walk with assistance, but dragged the left leg. The grasp of the left hand was much impaired, and the muscles generally were very flabby, especially on the left side. The respiratory movements were normal. The deep reflexes were present and the left knee-jerk was slightly increased The sensory phenomena were the more marked There was marked, but not complete, anæsthesia everywhere, except on the face, and that to all forms of stimulation. She complained of her feet feeling as cold as ice, yet they were found quite warm to the touch. On the 13th I dictated the following note to the clinical clerk: "To-day we find profound anæsthesia over almost all the cutaneous areas supplied by the spinal nerves, though a prick can be felt in the left leg and gentle pinching can be felt in the left upper arm, though not in the shoulder of the same side. The cutaneous areas supplied by the cranial nerves appear to be normal *To day, also, we note the greater weakness of the* left arm as compared with the right and the increase of patellar jerk. The left side of the chest and the left rectus abdominis do not act so well as the right, and generally the motor weakness is greater" On the 28th she went home at her own request. On August 5th and 6th she had to have her urine drawn off, and on the 7th she passed both urine and fæces into the bed. Her appetite remained good. On *the 9th the articulation was affected and there was dysphagia.* This got worse and on the 11th her breathing became laboured and she died from asphyxia.

The duration of the illness was thus much longer than in the case of the first patient described, lasting as it did about two and a half months from the first appearance of the numbness. Sensory phenomena were the earlier and the more pronounced, and at one time were so markedly unilateral as to lead me strongly to suspect functional disorder, but on examination I found that there were no deafness, no limitation of the field of vision, and no colour-blindness on the anæsthetic side—symptoms which, as Charcot points out, are fairly constant in hysterical hemianæsthesia. The spread of the anæsthesia was most irregular, while a striking feature in the case was the persistence of the deep reflexes and their actual increase on the left side.

In both of these cases I am confident that spinal myelitis, in the ordinary sense of the term, may be safely excluded, for the paralysis, both motor and sensory, was so marked and extensive that, if due to this condition, it must have been associated with a more unquestionable affection of the sphincters and with at least some tendency to the occurrence of bedsores

There is no doubt that the term used by Landry, "acute ascending palsy," carries with it the conception of a disease beginning below and affecting the parts in an upward *direction* until, the respiratory centres being affected, death ensues, and in many cases this doubtless is the course of the disease. Ross, however, holds that Landry used the term "ascending" not in this sense, but to indicate that the palsy was centripetal, affecting, that is, the distal part of the limb before the proximal. If, however, we bear in mind the peculiar relation of the spinal nerves to the limbs, which is such that those muscles which act on the distal part of the limb are innervated from a lower part of the spinal cord than that which presides over the more proximal muscles, we shall find that, even if it were an accurate conception of the disease that it is a process invading the spinal cord from below upwards, this tendency of the distal part of the limb to be affected before the proximal would be just what might be expected, and so the paralytic phenomena would be ascending both in the ordinary sense of the term and in that as interpreted by Ross. There are, however, some cogent reasons against an ascending spinal lesion—I use the term in its widest sense to include toxic processes—being an essential pathological conception for the clinical syndrome. Thus, in some cases, as in that of the naturalist Cuvier quoted by Fagge, the upper limbs were affected before the lower; in many cases the arms, affected *after* the legs, were affected *before* the abdominal muscles, and in my first case, with great weakness of the legs and arms, there was normal strength of the muscles of the shoulders, while the ponto-medullary centres, or the nerves leading from them, were affected, as indicated by the palsy of the sterno-mastoid, of the face, and of the external rectus. Most cases, however, are certainly characterised by a general extension of the paralysis from below upwards, as, indeed, my first case strikingly shows; but a progressively upward extending lesion, structural or nutritional, of the spinal cord, will not by itself account for all the phenomena of the disease, and in many cases would be strikingly at variance with those which are present.

By those who incline to the view that Landry's palsy must find a place in the class of peripheral neuritis or in a toxic condition affecting chiefly the peripheral nerves, it is pointed out that the little which is known of its causation points in that direction, for alcohol, exposure to cold, and exposure to the poison of the exanthemata, are probable causes of each, while the existence of splenic and glandular enlargement suggestive of some toxic process is common to both. This is certainly the view which commends itself most to my mind, and, as other points in favour of the two affections being classed together, I may mention the early shooting pains and malaise, the frequent march of the palsy from periphery to centre, and, above all, the varying combination of motor and sensory phenomena which is found in both affections. This latter variability is well known in peripheral neuritis. I may instance the painful palsy of alcoholic causation and the usually painless palsy of lead, both admittedly due to affections of the peripheral nerves, and which may fairly compare respectively with instances, such as those which I have related, in which the sensory phenomena were marked, and those more common cases where *sensation is less affected*. But that Landry's palsy cannot be accounted for by an affection of the peripheral nerves alone is almost certain. In my first case I note that the paralysis of the external rectus of the eye and of the face were on the same side, and from the known proximity of the sixth and seventh nuclei this is strongly suggestive of a central affection as against a peripheral affection.

There is no doubt that our conceptions of peripheral neuritis must be widened, and the researches of Dr. F. W. Mott and others on the anatomy and physiology of the neuron make it incumbent on us to enlarge the boundaries of this class of diseases, or possibly to re-label some of them. Thus when we say of anyone that he is suffering from alcoholic neuritis we neither express, nor do we overlook, the fact that the poison does not act only on the nerves, but that the centres in the cerebrum are also affected, and it is, of course, only in this sense of the term that I support the provisional classing of Landry's palsy in the group known as peripheral neuritis. And if, as Westphal was the first to suggest, the disease is due to an infective process, it is not unreasonable to hold that various parts of the nervous system may be affected in different cases, or even in one and the same case, for we are aware that poisons of known nature have a selective influence on various parts of the nervous system—morphia on the brain, strychnia on the cord, curara on the motor nerve endings, atropine on the eye, lead especially on the nerves of the extensor muscles of the forearm, and alcohol sometimes, I believe, on the motor nerves only, and at other times on the motor and the sensory nerves both as well as on nerve centres.

In one of my cases the knee-jerk was abolished, in the other it was increased, just as we find in different instances of alcoholic paralysis; and this seems to point to the probability of the lower motor neurons being affected in some cases and the upper in others. So, also, in the same case we have evidence in the great paralysis of the limbs, centripetal in character, and not associated with any affection of the sphincters, of a peripheral lesion, and at the same time evidence of a central lesion in the association of facial and ocular palsy on the same side.

It will be noted that in both the examples which I have recorded the sensory phenomena were early and well marked, and that in Case 2 they were for a long time far more striking than the motor phenomena. It is pointed out by Dr. Judson Bury that many writers exclude cases in which sensory phenomena are conspicuous, but he clearly shows from a reference to Landry's original paper that those who admit such cases (viz., Nauwerk and Barth and Ross) are more correct than those critics (Bailey and Ewing) who would exclude them; for Landry, while stating that generally motor symptoms predominate, also clearly expresses the view that "sensibility and mobility may be equally affected," and as Dr. Bury very cogently remarks, "If Landry's paralysis means anything, it means the disease originally described by Landry."

Leeds.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ACUTE RHEUMATISM WITH PREVIOUS MITRAL REGURGITATION FOLLOWED BY PERICARDITIS.

By ALBERT R. HENCHLEY, L.R.C.P., L.R.C.S. EDIN., L.F.P.S. GLASG.

IN March, 1900, I was attending a boy in this village suffering from acute rheumatism with mitral regurgitation, and during the latter part of his illness, when he was practically convalescent, the mother asked me if I would call and see another son of hers the next day in a village a mile away. On arriving there the following day (March 26th) I found the lad, aged 17½ years, in bed, with both knees and ankles and the left shoulder swollen and painful. He said that he had been bad for seven or eight days with first one joint swollen and then another, and thinking he had "caught a chill" he had hoped that it would pass off. *His temperature was 103° F.*, his respirations were 28, and his pulse was 90 His bowels had been open twice that morning but previously they had been confined. He was sweating freely. On examining the chest I found that the area of cardiac dulness was increased, the impulse being in the fifth left interspace, below and slightly external to the nipple. There was a well-marked mitral systolic murmur which was to be heard distinctly in the back of the same side. His previous illnesses were measles and (?) scarlet fever, the latter when he was about three years of age, and the medical man in attendance then is said to have remarked that it had affected his heart. Nine months previously I had refused to pass him into a friendly society on account of his having a systolic murmur at the apex.

I had the joints covered with cotton-wool and flannel. I also advised bathing his chest and head with tepid water and gave him a mixture containing 10 grains of sodium salicylate, 10 grains of potassium bicarbonate, and four minims of tincture of digitalis, to be taken every four hours, and two teaspoonfuls of brandy, also every four hours. By April 1st his temperature had dropped to 100°, his pulse was 90 and his respirations were 30. No other joints had been affected in the meanwhile, but those that were had considerably lessened in size and he was suffering from no pain. On examination of the heart I found it to be considerably increased in size, reaching to the right of the right border of the sternum, above nearly to the lower borders of the second ribs, and practically as before on the left side. Friction sounds were to be heard over this area By the 3rd the joints were normal in size and painless and the sweating had subsided, but the temperature had risen to 103·2°, the pulse was 120, and the respirations were 40 The urine was diminished in quantity to 44 ounces in 24 hours I stopped the sodium salicylate and substituted 30 grains of diuretin every four hours. The brandy was continued and the bathing was stopped. The patient was kept propped up in bed almost at right angles to it, as otherwise orthopnœa was so pronounced. During the next five days, with occasional small doses of antifebrin, the temperature dropped to 101°, but there were no signs of absorption of the effusion taking place I ordered the chest to be painted once daily with tincture of iodine (half strength) and gave three grains of iodide of potassium every four hours By the 12th the area of cardiac dulness was markedly diminished; the temperature was 99·4° in the morning and 100·2° in the evening. The urine had now reached about 60 ounces daily. The painting of the chest with iodine and the administration of iodide of potassium were stopped, as an iodide rash had appeared. On the 20th the patient's temperature was normal and remained so, and his heart had resumed its normal size. He was, of course, still kept in bed and all available and suitable nourishment was administered. In the beginning of June the parents particularly wished him to be taken home. A carriage and pair was kindly lent and he was placed on a stretcher and put in it and taken at a walking pace. A few days afterwards I was fetched early in the morning to him and found that he had commencing signs of backward pressure from the heart failing The lungs were congested at the bases, the liver was enlarged, and there was œdema of the legs, ankles, and feet. I gave him a hypodermic injection of one-hundredth of a grain of strychnine sulphate and ordered half a wineglassful of champagne every two hours. The next day he seemed much better and was ordered a mixture of digitalis and an alkaline aperient Then he developed a sudden swelling of the left forearm and hand with simple phlebitis, probably due to thrombosis of the axillary vein; the right arm being quite normal in size In the course of 10 days this got better, but otherwise he became gradually worse and he died on June 26th.

Now that there is so much discussion on the classification of acute rheumatism it seems worth while drawing attention to the coincidence of two members of the same family being affected at the same time Although not living in the same house the deceased had visited his brother frequently before he had to take to his bed I believe it is not a common occurrence to recover from pericarditis when there is a previous diseased condition of the valves of the heart.

Blagdon, near Bristol.

A CASE OF COMPLETE INVERSION OF THE UTERUS

BY DAVID DURRAN, M B. GLASG.

OWING to its great rarity the following case of complete inversion of the uterus ought to be placed on record. According to Playfair this accident was only observed once in upwards of 190,800 deliveries at the Rotunda Hospital since its foundation in 1745. Various explanations have been given to account for its production. In the present case there was a suspicion that pressure on the abdomen was improperly applied, but the midwife who was in attendance would not admit that there was undue pulling on the cord. The case was as follows.

On Jan 30th, 1899, I was called to a woman in labour. On my arrival I found her in bed, pale, with a small and feeble pulse, cold clammy skin, and evidently suffering from shock The midwife informed me that a little over an hour before a child was born and that along with the after-birth something came down the like of which she had never seen before but which she thought was the womb This she returned. There was great loss of blood and the patient had been in a fainting condition ever since. It may be mentioned here that the patient was 25 years of age, strong, and in good health. She had been married seven years and this was her third child. On examination I discovered a large globular mass of the consistence of muscle tissue filling the vagina and bleeding profusely. Bimanual examination showed the absence of the contracted uterus and instead a cup-shaped depression was easily felt, which made out the case to be one of complete inversion of the uterus. Manipulation restored the organ in a few minutes to its natural condition. The inverted uterus was first firmly grasped by the hand and gently squeezed, being at the same time pushed slightly upwards The tips of the fingers were then applied to the fundus and by steady pressure in the proper axis of the pelvis the uterus was felt to resume its natural shape. The patient made a good recovery and everything went on well until the eleventh day after the confinement, when delusions showed themselves, and in a few days the case developed into one of acute puerperal mania presenting the usual symptoms, which necessitated asylum treatment There was evidence of hereditary tendency, but the determining cause at that time was no doubt the shock from the accident referred to as well as exhaustion from the great loss of blood After several months in the asylum the patient returned home and is now in very good health.

Thurso, Caithness.

UNUSUAL CONDITIONS AT BIRTH.

BY A J. RICE OXLEY, M.A. OXON., M.B. DUB., M.R C S ENG.

CASE 1. *Fracture of the clavicle: normal presentation.*—A patient of mine was delivered of her third child a short time ago. At my visit the following day the nurse asked me to look at a "sharp hard swelling at the top of the right side of the chest." On examination I found that the infant had a fractured clavicle. Delivery had been very rapid—so rapid that I was unable to arrive in time; but the nurse, a skilful one, assured me that she had in no way interfered during the progress and that it was normal in every way "except for its being very quick indeed" Such an occurrence is, of course, not very remarkable in some cases of difficult labour, but is surely very unusual in a case of the above-mentioned type, I may add that union was quite satisfactory.

CASE 2 *Congenital thickening of the sterno-mastoid.*—Shortly after delivery (by forceps) the nurse called my attention to a lump at the side of the neck of the infant. I had exercised comparatively little traction and diagnosed the case as "congenital swelling of the sterno-mastoid." This thickening was not a hæmatoma I am sure, and has now almost disappeared without any limitation of movement. I gave small doses of grey powder, but as the tendency of these thickenings is to clear up by themselves it is impossible to ascribe any definite effect to this preparation.

Streatham, S W.

PROPOSED BACTERIOLOGICAL LABORATORY.—The sanitary committee of the Plymouth Corporation have decided to approach the Devon and Cornwall County Councils and the Stonehouse District Council in reference to the formulating of a scheme for the establishment of a joint county and municipal bacteriological laboratory in conjunction with the borough of Plymouth

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF TETANUS; SUBDURAL INJECTION OF ANTI-TETANIC SERUM; RECOVERY.

(Under the care of Mr. A. E. Barker.)

In the present state of our knowledge as to the therapeutic value of the intracranial injection of anti-tetanic serum it is very desirable that as many cases as possible of this ingenious treatment should be put on record. The injection of the serum into the subdural space is simpler and less likely to do harm than the injection into the brain substance, and therefore is to be preferred if it seems to be equal in efficacy. Of 25 cases that have been recorded of treatment by intracranial injections, 14 patients died and 11 recovered.[1] For the notes of this case we are indebted to Mr. Percy Stedman, house surgeon.

A man was admitted into University College Hospital under the care of Mr. Barker on May 4th with the following history. 14 days previously he went into his yard, slipped down, and cut the side of his head. A friend washed the wound for him with Condy's fluid and bandaged it up. He felt little the worse for the fall and went on with his work as usual until May 1st. On this day he felt that his neck was getting stiff and he experienced a curious sensation of something crawling up the back of his neck; he saw his medical adviser who sent him to bed. On the next day the stiffness at the back of the neck had increased and the head was twisted to the left side. The following day the jaw and also the back of the legs began to get stiff. He had no twitchings or convulsions.

On admission, on the right side of the head, over the lower and posterior part of the parietal bone, was a wound through the skin, about one square inch in size. It had a distinctly sloughy appearance and around it there was a large amount of œdema. He complained of pain and stiffness at the back of his neck and of inability to open his mouth; he could not turn his head to the right, neither could he raise himself from the bed. The back was arched and the legs were rigid; he perspired very freely, being covered with beads of sweat. On making an effort the patient was able to open his teeth to the extent of a quarter of an inch: through this a small indiarubber tube had been inserted by which the patient was fed with milk. The arms were unaffected, the thorax and abdomen moved well on respiration, but the abdominal muscles were rather hard. The pulse, respiration, and temperature were normal.

In the absence of Mr. Barker from town Mr. Victor Horsley decided to inject anti-tetanic serum. The head was shaved over the parietal bone and the sloughy wound was excised. The skull was trephined with a quarter-inch trephine and the needle of the injection syringe was passed into the sub-dural space and seven and a half cubic centimetres of anti-tetanic serum, prepared at the Jenner Institute, were injected Whilst the patient was under the anæsthetic the spasm of the muscles only showed slight tendency to relax. During the following four days 20 cubic centimetres of serum were injected into the flanks. The abdomen became very rigid and the right arm also became rigid. Gradually increasing doses of chloral had been administered to the patient since his admission until he was taking 60 grains per diem: this was continued.

No improvement took place for a week when the rigidity of the muscles of the neck and abdomen began to pass off. From this time onward the patient made an uninterrupted recovery, the rigidity passing from the legs last, and at the end of three weeks from his admission into the hospital all the stiffness had passed off.

ROTHERHAM HOSPITAL.

A CASE OF TUBAL GESTATION WITH RUPTURE IN A WOMAN PREVIOUSLY OPERATED UPON FOR TUBAL GESTATION WITH MISSED LABOUR.

(Under the care of Mr. J. B. Lyth.)

One of the more frequent causes of sterility in women is an obstruction to the passage of the ovum along the Fallopian tube. If this obstruction be bilateral and complete the sterility is absolute, but if it be unilateral, or not complete, fertilisation may occur. This is then especially likely to take place in the Fallopian tube, for the spermatozoon can pass through an opening which is too small to allow the passage of an ovum. For the notes of the case we are indebted to Dr. J. S. Martin, house surgeon.

A married woman who had had one child born dead 10 years previously was admitted into the Leeds Infirmary in November, 1892, under the care of Dr. James Braithwaite, to whose courtesy Dr. Martin is indebted for an account of her case while there. She had a history of 10 months' pregnancy. There was no history of rupture of the sac. After nine months the child appeared to have died. On Nov. 30th an operation was undertaken and a large full-grown dead child was removed. It lay in a cyst which was an expanded portion of the left broad ligament. The placenta was attached to its posterior wall and was removed. The edges of the cyst were stitched to the peritoneum, the cavity was drained, and the patient made a good recovery. She had no further pregnancies and remained well until six weeks before her admission to the Rotherham Hospital. She had some irregular hæmorrhages and these in the light of her previous experience she regarded as evidence that she was again pregnant. She thought that she would be three or four months gone. Six weeks before admission she had an attack of abdominal pain with collapse, sickness, and jaundice. The attack lasted a couple of days. She had six attacks before her admission. On May 22nd, 1900, and on the morning of the 23rd she had another attack. She was in great pain and her blanched lips and feeble pulse indicated internal hæmorrhage. Her temperature sank to 96° F. An injection of strychnine was given and a quarter of an hour afterwards she rallied. The pain and sickness continued through the day. On the following day (May 24th) she was better and it was possible to make an examination of the abdomen. There was a tumour reaching well above the umbilicus and lying medially but somewhat inclined to the right. The scar of the previous operation lay to the left of the umbilicus. In the afternoon she had another attack similar to that of the 23rd. She recovered again and on the 26th she was so much better that Mr. Lyth proceeded to operate.

An incision was made, starting from a point one inch below and to the right of the umbilicus, and continued downwards for about three and a half inches. On opening the peritoneum a mass of blood-clot came into view. Mr. Lyth passed his hand first around and then through this and his hand entered the sac. Placental tissue and a piece of umbilical cord four inches in length were found, but no fœtus. The pregnancy was in the fimbriated end of the right Fallopian tube or between it and the ovary. The sac had in the course of its growth become adherent to the omentum, the wall of the pelvis, the small intestine, and the posterior part of the body of the uterus. The uterine end of the Fallopian tube had become adherent to the sac. Between this and the fimbriated extremity there was a free loop. The placenta lay upon the upper surface of the sac. The site of the rupture could not be discovered. Before a pedicle could be made it was necessary to remove the placenta. After this all the free portions of the sac were cut away. Two portions of the sac were so closely adherent to the omentum and the pelvic wall that it was necessary to leave them. From the size of the sac the pregnancy was about the fifth month. During the operation the patient lost a good deal of blood and saline infusion was resorted to. A glass drainage-tube was inserted and the wound was closed.

The patient made a good recovery. The wound was syringed daily with a solution of boroglyceride (1 in 20). There was diarrhœa from May 30th to June 2nd, which was probably the result of absorption of septic products On June 1st the tube was removed and the wound was closed. On the morning of the 4th the temperature rose to 99 4°. This led to an examination of the wound and the discovery of a localised abscess containing a good deal of offensive purulent matter. This was evacuated, a rubber drainage tube was inserted, and the cavity was syringed with iodoform emulsion. The wound was now dressed daily, pieces of placental tissue coming away from time to time. The tube was removed on July 2nd and the wound was completely healed on July 26th, the date of her discharge

---

[1] Practitioner, 1899, vol. ii, p. 80

Remarks by Dr. MARTIN.—The above case may be of interest not alone on account of its rarity but as illustrating the fact that some women are liable to abnormalities of gestation on both sides of the body. Such cases would point to some abnormality in the formation of the uterine appendages delaying the passage of the ovum rather than to accidental causes. Greig Smith in his "Abdominal Surgery"[1] mentions some six or more cases recorded by various observers. In the same work he states that the condition is likely to occur in women who have been sterile for long periods or who have shown "inaptitude for conception." This statement is borne out in the above case, there being an interval of 10 years between the first and second pregnancies and one of eight years between the second and third Neither at the first nor at the second operation was any malformation of the uterus or tubes observed, but it is possible that under the circumstances such malformation may have been overlooked. I am indebted to Mr. Lyth for permission to publish the case and to Dr. Braithwaite for the permission to use the notes which he kindly sent me.

SALOP INFIRMARY.

A CASE OF INTRA THORACIC GROWTH SIMULATING HEART DISEASE

(Under the care of Dr E. CURETON)

THE diagnosis of mediastinal tumours is always attended with difficulty, and the growths may attain a large size before being recognised. The physical signs usually point to localised pleural effusions or to pulmonary consolidation; occasionally, as in the case recorded below, the interference with the heart's action may lead to signs suggestive of disease of that organ. A few cases have been recorded in which an intra-thoracic growth has given a fairly distinct shadow on a Roentgen ray photograph, and we may hope that by improvement in skiagraphy the diagnosis of these tumours may be simplified

A man, aged 27 years, was admitted into the Salop Infirmary on July 7th, 1900. The patient had had shortness of breath for three months and pain in the præcordial region for six months; both pain and dyspnœa had become worse during the last month The patient stated that he had never had rheumatism or chorea

On examination the upper border of the heart was found to be at the third rib, the right border was at the right edge of the sternum, and the left border was just external to the left nipple. The impulse was forcible and heaving and was best felt in the fifth space one inch internal to the left nipple. A loud systolic murmur was heard at the apex and conducted into the axilla; a systolic murmur was heard at both bases and conducted to each clavicle, the second sounds were clear A systolic murmur was heard over the middle of each lung. The pulse was irregular and strong and the radial artery felt thickened The feet had been swollen and were slightly so on admission The left lung was duller on percussion in front and behind than the right, and the heart sounds were not so clear The sounds heard in the axilla were natural There were no adventitious sounds. The subsequent history of this patient up to his sudden death on July 12th was uneventful; he appeared to be better and asked to be allowed to go home.

Necropsy —On post-mortem examination the mediastinum was found to be filled with a mass of new growth involving the glands at the root of the lung and surrounding the base of the heart and great vessels. The growth extended into the neck on each side of the trachea and on the left side along the subclavian artery, being firmly adherent to the tissues at the back of the clavicle The left lung was to a large extent taken up by the growth except in the axillary border, and there was a patch of old pleural adhesions over the upper third in front and in the axilla. The heart was pushed forward and hypertrophied, the pericardium was thickened and adherent, and the coronary veins were enlarged and very tortuous In the pericardium there were patches of new growth, but the heart muscle was not apparently implicated No valvular lesions were found. The parietal pleura on the left side was studded with the growth, as was also the diaphragm New growth was found in the pancreas, both in the head and in the tail, which was adherent to a mass of growth involving the left suprarenal capsule; there were also some patches in the capsule of the left kidney. The remaining abdominal viscera appeared to be normal.

Remarks by Dr. CURETON —*The growth described above* has been examined by the pathologist to the hospital Mr. T. L Webb, and pronounced to be a lympho-sarcoma. For the above recorded notes I wish to thank our deputy house physician, Dr. Cecil Reynolds.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

After-results of Vaginal Hysterectomy performed for Cancer of the Uterus.

A MEETING of this society was held on Nov. 13th, Dr. F. W. PAVY, the President, being in the chair.

Dr. A H. N LEWERS read a paper on the After-results in Forty Consecutive Cases of Vaginal Hysterectomy performed for Cancer of the Uterus. He grouped the cases as follows: in 12 cases there had been no recurrence; in 18 cases there had been recurrence; four cases had died; in two cases the nature of the disease could not be proved by examination of the specimens; in three cases no definite information was obtained as to recurrence; and in one case the disease proved to be primary tuberculous ulceration of the cervix. Omitting Case 39, in which little more than a year had elapsed (without recurrence), there were 11 cases (or 27 5 per cent) remaining well from two to more than seven years subsequent to the operation. Dr. Lewers believed that this high percentage was largely due to the careful selection of cases. His rule had been to examine under anæsthesia and only to operate on those cases in which, according to the physical examination, the disease seemed to be limited to the uterus itself, and he had for *some time* past *only* performed the supra-vaginal amputation of the cervix for very early cases and cancer of the vaginal portion, in which there was a limited and superficial growth. He had performed 33 amputations of this kind, but these were not included in the paper. In each of the 12 cases of vaginal hysterectomy in which the disease had not recurred the specimen had been independently reported on by Mr J. H. Targett (of the Clinical Research Association), and his report was given in the paper. In each of the same 12 cases full details were given also of the evidence on which it was claimed that the disease had not recurred. Dr. Lewers believed that on this point the evidence was more precise and in fuller detail than had been given previously, over a series of cases The conclusions arrived at from a consideration of the cases reported in the paper were as *follows*: 1. That in a certain proportion of cases patients suffering from cancer of the uterus might be relieved by operation for periods of many years—in some cases for so long a time, seven years and upwards, that there seemed a probability that the relief might be permanent 2 The proportion of cases in which this result could be expected must remain very small so long as patients generally only sought advice at a late stage of the disease. 3 The great desideratum was early diagnosis. Especially important was the more general recognition of the gravity of bleeding occurring after the menopause, or, at an earlier period of life, between the menstrual periods. It was almost equally important to bear in mind that patients suffering from cancer of the uterus might, and generally did for a relatively long period, look quite well; and they might appear to be well nourished, and even fat Two later passed a great quantity involuntarily. An interesting feature about this family was that the father presented ataxy, various sensory perversions, gastric crises, and slight ptosis in one eyelid.—Dr. EWART remarked that some of the features of the case suggested Friedreich's ataxy in an early stage and he proposed that the case be referred to the committee.—Mr. WEEKS, in reply, said that the absence of nystagmus and tremor was rather against Friedreich's disease.

---

[1] Vol. I, p. 4[illegible]

Dr. MORGAN DOCKRELL exhibited two cases of Adenoma Sebaceum, one in a child, aged six years, and the other in a woman, aged 24 years. In both the condition was congenital. There were a number of small sebaceous tumours of about the size of millet seeds over which the skin presented telangiectasis. They had started and were most plentiful, as usual, on the face. Some years ago, when he had been looking up the subject, there were only 10 cases recorded, but at the present time there were some four or five cases attending St John's Hospital. There were two interesting features about these cases. In the first place, it was generally believed that the disease was associated with the occurrence of fits and a want of intelligence, but in neither of these cases did these features exist. In the second place, a warty condition was usually thought to be associated with the disease, but in neither of these patients was there any lesion of the kind. He had carefully studied the histology of these cases and coloured sketches, photographs, and microscopical specimens were exhibited showing that it was a true adenoma of the sebaceous glands. There was marked dilatation of the lumen of the blood-vessels corresponding to the telangiectasis.—Dr. JAMES GALLOWAY remarked that it was very interesting to observe two cases illustrating different stages of this rare affection. The disease ought to be regarded as a congenital defect in the development of the skin rather than a subsequent overgrowth. It was not really overgrowth though there was enlargement of the vessels. The term "adenoma sebaceum" was not a suitable one. It had been adopted before the pathology of the disease had been studied.—Dr. ALFRED EDDOWES referred to a case under his care. The child was exceptionally bright and intelligent.—Dr. DOCKRELL, in reply, pointed out that the microscopical examination showed a true adenomatous growth. There was an overgrowth without any loss of the tubuli or acini of the glands.

Dr. DOCKRELL also showed a case of Hyaline Degeneration of the Skin (a condition which corresponded somewhat to the colloid milium of Besnier). The patient was 20 years of age and she had had all her life small translucent waxy tumours beneath her eyelids. The case was a unique one and he had the opportunity to study the histology of the affection. The change was not an adenomatous one, but there was cystic enlargement of the glands, the cysts being distended with hyaline material. Dr. Unna had expressed the opinion upon the microscopical specimens from the case which had been submitted to him that the change was not adenoma but a special hyaline degeneration of the connective tissue, "a special disease of the coil glands and surrounding tissue undergoing first hypertrophy and then degeneration." Microscopical specimens and drawings were exhibited.—Dr. GALLOWAY remarked that cases resembling this had been shown at the Dermatological Society He complimented Dr. Dockrell upon the microscopical specimens exhibited. Owing to the newer methods, by the use of acid aniline stains which he had employed the histological condition had been revealed. The specimens undoubtedly showed that the elastic tissue had undergone degeneration. The elastic fibres were broken and they were swollen at the ends. The term "hyaline degeneration" had been applied very irregularly to indicate what was sometimes called hyaloid or vitreous changes The process of hardening had to be taken into consideration. He was glad that Dr Dockrell had drawn attention to the coil glands; it was only in these and in their neighbourhood that the degeneration took place. The disease was probably clinically allied to what had been previously spoken of as xanthelasma, colloid, or colloid milium.—Dr. DOCKRELL, in replying, remarked that no doubt there were cases which might resemble this one clinically, but unless histological examinations were made it was not possible to come to a conclusion as to their identity or not. He wished to emphasise the importance of making microscopic examination in all cases, when a very marked difference would be found to exist. As to the point that there was any uncertainty in diagnosing hyaline and colloid degeneration, it must be remembered that there were many different forms of hyaline degeneration, such as that found in actinomycosis, that found in lupus erythematosus, and in lichen planus; but in all cases it was easy to diagnose it from true colloid material under the microscope. He hoped on a future occasion to exhibit a case presenting the clinical appearances of xanthoma though histologically showing a colloid condition of the sebaceous glands with a hyaline appearance of the coil glands and connective tissue.

Mr. WALLIS showed a case of Baker's Cyst in a man, aged 44 years. He presented a swelling just below the left knee; the joint also contained fluid. The fluid aspirated from the swelling exactly resembled synovia, but there was no apparent communication with the knee-joint. Scars of old syphilitic lesions in the skin were to be seen on both legs of the patient.

Dr. A. EDDOWES exhibited a man, aged 47 years, presenting Coronal Baldness of 15 years' duration combined with alopecia areata of 18 months' duration, the latter having started on the skin.

The PRESIDENT exhibited a Deformity of the Tibia in a boy, aged 16 years. One and a half years ago he had been injured while jumping. The limb subsequently gave him some trouble and splints were applied. Now there was swelling of the foot due to outward curvature of the tibia, indicating that some injury had happened to the epiphysis, probably a fracture.

CLINICAL SOCIETY OF LONDON.

Sequel to a Case of Hydatid of the Liver.—The Mid-Diastolic Murmur.

A MEETING of this society was held on Nov. 9th, Sir R. DOUGLAS POWELL, the President, being in the chair.

Dr. NORMAN DALTON read a paper on the Sequel to a Case of Hydatid of the Liver, showing also the result of abdominal section on ascites The patient was a girl who, at the age of 11 years, was under the care of Dr. Thomas Barlow at the Hospital for Sick Children, Great Ormond-street, for hydatids of the liver. While in the hospital she passed hydatids per rectum and also expectorated bile from the right lung. She recovered and remained well until the age of 16 years, when ascites set in, and she was admitted into King's College Hospital under the care of Dr. Dalton. After a time it became necessary to tap the abdomen every fortnight, so an exploratory abdominal section was performed by Mr. Watson Cheyne in the hope that a new hydatid, or some remains of the old, might be found and removed. However, nothing which could be removed was found, but it was noticeable that no adhesions were present except at the top of the liver round the fistula into the lung. The wound healed well, but paracentesis was necessary twice in the first fortnight after the operation. After this, however, the ascites did not recur and the patient was quite well for five years. Examination during this time showed that a small quantity of fluid remained in the hypogastrium, while the rest of the peritoneal cavity was thought to be obliterated by adhesions. In May, 1899, the patient died at the age of 23 years from septic peritonitis, which appeared to be due to bruising of the intestines in a ventral hernia at the site of the operation scar. At the post-mortem examination the old cyst was found in the liver, communicating below with a dilated bile duct and above, through the diaphragm, with a dilated bronchial tube. Glisson's capsule was greatly thickened and the liver showed a cirrhosis which had spread from Glisson's capsule inwards. The peritoneal cavity was obliterated by old fibrous adhesions, except in the hypogastrium, where there was a collection of turbid fluid. There were also a few loculi among the intestines and these contained pus. The omentum and mesentery were short, thick, and fibrous, showing chronic peritonitis. It seemed probable that the almost complete cure of the ascites was due to the formation of extensive adhesions, which Dr. Dalton believed would not merely stop the ascites by mechanically filling up the peritoneal cavity, but would really relieve the portal congestion by opening up communications between the portal capillaries and those which joined the veins in the abdominal wall. Dr. Dalton also thought that the cause of the extensive adhesion was the exposure to the air of the endothelium which covered the peritoneum. In ascites this endothelium was ill-nourished and any irritation might lead to the formation of adhesions. In support of this idea was the fact that cases of tuberculous peritonitis in which ascites was present were often cured by abdominal section; and presumably in those cures extensive adhesions formed. This case distinctly encouraged the plan of treating the ascites of cirrhosis of the liver by abdominal section because for the last 10 years of the patient's life the hydatid was practically cured and the condition was really that of cirrhosis of the liver.—The PRESIDENT remarked, *à propos* of the effect which adhesions had in preventing the occurrence of ascites, that he had noticed that cases of cirrhotic ascites presented a better prognosis when there was an unequal distribution of fluid. He mentioned such a case in which after several tappings the ascites disappeared altogether. In the end this case terminated somewhat like the one brought before the society. The patient was suddenly seized with severe pain and generalised peritonitis and died in a few days, the seizure being probably due to a laceration of the adhesions, followed by hæmorrhage into the abdominal cavity. He agreed with the suggestion that the favourable course pursued by cases with adhesions was due to the establishment of a collateral circulation.—Mr. HOWARD MARSH remarked that the subject was important in relation to the new method of treating ascites by the artificial production of adhesions after the manner adopted by Mr. Rutherford Morison of Newcastle. Laparotomy was performed and the omentum was fastened to the abdominal wall so as to make artificial adhesions. He had done the operation himself on one occasion successfully and he believed that several of Mr. Morison's cases were successful.—Dr H D. ROLLESTON wished to draw attention to the rationale by which adhesions relieved both the ascites and the other symptoms in cases of cirrhosis of the liver. Mr. G R. Turner and himself had brought the subject before the Medical Society last year and they had collected some 15 cases in which operation had been performed.[1] After a study of these cases they had come to the conclusion that it was not only by the production of a collateral circulation that benefit was conferred. It was not only the ascites but the patient's other symptoms which were relieved, and this latter could not be accounted for by the establishment of the collateral circulation, for animals in which the portal and the general circulation were joined became uræmic, and Mr Morison himself had noticed that the patients became low after operation. He suggested that artificial peritoneal adhesions brought more blood to the surface of the liver and so improved its nutrition, as the result of which compensatory hyperplasia of the liver took place.—Dr. ALEXANDER MORISON assumed that general adhesions such as those described by Dr. Norman Dalton acted by limiting abdominal expansion and inducing an increase of thoracic aspiration. While not questioning the possible correctness of views entertained by surgeons as to the service capable of being rendered to absorption from the peritoneal cavity by establishing a collateral circulation through adhesions, he believed this contention remained to be proved. On the other hand, striking effects in the removal or cure of recurrent ascites might be witnessed by such a complete circular strapping of the abdominal cavity after paracentesis as prevented that cavity expanding and which of necessity lead to exaggerated thoracic aspiration. He quoted cases in support of his contention and suggested that the more general adoption of the method he advised would obviate the necessity for recourse being had to the methods recommended by some surgeons—Dr. F. S. TOOGOOD referred to a patient who was admitted into the Lewisham Infirmary in March, 1893, with a history of hæmatemesis and melaena who had been tapped every two weeks, several pints of fluid being removed He performed Mr. Rutherford Morison's operation upon this patient, but in the following September she developed a strangulated ventral hernia through the cicatrix This was operated upon and four months later another hernia occurred, but there was no recurrence of the ascites after the artificial adhesions had been produced The liver when touched at the operation had felt typically hobnailed —Dr NORMAN DALTON, in reply, pointed out that the production of adhesions was not quite equivalent to the establishment of direct venous connexion because in the former the blood passed through the capillaries before entering the circulation Hernia was undoubtedly one of the dangers in these cases of ascites treated by operation. He mentioned a patient who died from ventral hernia and remarked on the difficulty of obtaining a tightly closed wound.

Dr. T. STACEY WILSON read a paper on the Diastolic Cardiac Sound which caused Spurious Reduplication of the Second Sound at the Apex (sometimes called the third sound of the heart). The paper was illustrated by numerous cardiograms and it was based upon two cases which were narrated. The sound under discussion was known also as the mid-diastolic murmur. He accepted the theory that the diastolic sound was in all probability caused by the passage of blood through the mitral valve at the commencement of the diastole. The cardiographic tracings showed that the second sound occurred at or just after the commencement of the diastole; they also showed that the third sound occurred at the commencement of the period of muscular relaxation and this marked the commencement of the third phase of the ventricular cycle. The first sound marked the commencement of ventricular contraction, the second sound marked the commencement of ventricular expansion, and the third sound marked the commencement of ventricular relaxation. In cases where the third sound was well marked the cardiogram would exhibit a short, sharp rise immediately following the fall due to muscular relaxation. This oscillation he proposed to call the "suction recoil wave." A study of this wave showed that in cases where the third sound existed there was evidence of increase of tension within the ventricle just after the onset of ventricular relaxation. Dr. Wilson's method consisted of listening himself to the cardiac sounds while he worked the time recorder, an assistant superintending meanwhile the cardiographic tracings. His observations went to show that the mid-diastolic murmur, or, as he preferred to call it, the third sound of the heart, would occur—(1) whenever there was a narrowing of the mitral orifice; or (2) whenever the auricle held more blood than the ventricle could draw through the normal mitral orifice during its expansion movement; and these conditions would occur in (1) mitral stenosis; or (2) whenever the auricle was dilated so as to hold more blood than the ventricle; or (3) probably whenever the ventricular muscle was too weak to empty the auricle as rapidly as normal. In support of these propositions he showed cardiograms from several cases of mitral disease in which the third sound was well marked and dwelt at some length upon one case in particular which threw considerable light upon the cause and meaning of this sound. The case was that of a girl who suffered from mitral regurgitation and pericarditis and in whom there was a well-marked third sound. The cardiogram was of a peculiar description and instead of showing the usual small recoil wave following the diastolic fall of the lever of the cardiograph it showed an extremely prominent one consisting in a pointed elevation nearly as high as the systolic rise itself. This was evident all over the heart and its occurrence seemed to give conclusive evidence that after the onset of muscular relaxation the ventricle was distended and subsided again. The force producing this diastolic distension of the ventricle being its own aspiratory action on the blood in the auricle, the child did not suffer from the ordinary symptoms associated with mitral regurgitation. There was no dropsy or cyanosis, but her symptoms more resembled aortic disease, especially in so far as pallor, faintness, and anginous pains were concerned. She died in a syncopal attack and at the necropsy it was found that there was mitral incompetence but no stenosis, in spite of the presence of the third sound. There was no dilatation of the left ventricle or of the right side of the heart The left auricle was, however, greatly dilated, holding nearly twice as much as the ventricle. The absence of compensatory dilatation of the ventricle was no doubt due to the adhesion of the pericardium and explained the anomalous symptoms during life —Dr H. D. ROLLESTON was glad to find that Dr. Wilson's observations confirmed the hypothesis suggested in a contribution by himself and Professor Roy in a paper published in the *Journal of Physiology* in 1887, in which they had found that the negative pressure in the ventricle amounted to something like 60 millimetres of mercury—an equivalent of quite half the driving force (positive pressure) of the ventricle. He suggested that the mid diastolic murmur was due to this suction action of the left ventricle Dr. A. L. Galabin in 1873 had attributed this murmur to the irregular contraction of the auricle, but Dr. Wilson's cardiograms confirmed the view that it was due to the action of the left ventricle He much preferred the term "mid-diastolic murmur" as being a more suitable term than the "third heart sound."—Dr. A E SANSOM remarked that he did not

---

[1] THE LANCET, Dec 16th, 1899, p. 1660 "Surgical Treatment of the Ascites of Cirrhosis by the Artificial Production of Peritoneal Adhesions."

like the term "third heart sound" because the sound did not belong to the normal heart. It was a murmur interpolated in the diastolic period, and it was only heard under morbid conditions. It was one of considerable practical importance. There were several kinds of sounds heard in this the diastolic period. In the first place there was what was called the reduplicated second sound; secondly, there was the series of murmurs described by Bristowe as early, middle, and late diastolic sounds; and thirdly, there was what was known as the cantering rhythm of the heart. All observers were agreed that the reduplicated second sound had its origin at the mitral orifice, and he (Dr. Sansom) believed that it generally indicated (at any rate, in a young subject) the supervention of mitral stenosis; he believed that its causation was the suction action of the ventricle. But sometimes the murmur might be due to adhesions; it might also be due to enlargement of the ventricle or the auricle might be too weak or too strong.—Dr. A. **Morison** thought that in discussing this subject they should be certain that different speakers had the same phenomena in mind. He drew a sharp distinction between the reduplicated second sound heard at the apex in mitral constrictions and any form of so called cantering rhythm or bruit de galop He had been in some doubt as to the phenomena which the author of the paper had in view until he heard him phonetically imitate the sound he desired to explain. It appeared to him that the sound which Dr. Wilson imputed to the inrush of blood from the auricle during diastole against the mitral segments was in reality a phenomenon to be accounted for by the transmission to the apex of an accentuated and reduplicated basic second sound, obscured at the base and modified in tone by such transmission. The careful observation of tone or timbre of sound he thought of the highest importance in this connexion. He regretted that he could not agree with Dr. Sansom that the audibility of such a sound in the scapulo-vertebral region, especially in young subjects, indicated a mitral situation as its place of origin. He purposely refrained from the discussion of any form of cantering rhythm—a phenomenon associated with other conditions than mitral disease —which he thought could be otherwise accounted for than on the hypothesis advanced by Dr. Wilson.—Dr. **Seymour Taylor** remarked that the subject was not yet altogether worked out but in all probability the sound under discussion indicated mitral stenosis. He thought that the inrush of blood during the diastolic period might be likened to the rush of people into a theatre. He did not like the term "reduplicated second sound," because the sound, however caused, was essentially pathological. All murmurs were produced by muscular force and their intensity depended upon the force behind it. It followed, therefore, that a loud murmur in mitral stenosis was a good sign. When the murmur disappeared it indicated that the auricle and ventricle were becoming weak.—The **President** remarked upon the intricacy of the subject. He would like to know the relation of the sounds described by Dr. Wilson to the cardiac impulse.—Dr. **Forbes Ross** remarked that he could not quite follow Dr. Wilson's descriptions How was it possible that the valves could be kept tense by muscular relaxation? A presystolic murmur was often called a rough first sound and he believed that many of these obscure murmurs might be caused by roughening of the pericardium.—Dr. **Wilson**, in reply, remarked that without doubt a great variety of murmurs could be heard which were produced outside the heart. The murmur to which he referred corresponded to one of the forms of the cantering bruit. As a rule, the presence of the third sound to which he referred was an indication of mitral stenosis. He believed that the filling of the ventricle was entirely due to ventricular suction, excepting just at the end of the diastole.

Dr. **Hugh Thursfield** exhibited a child of about seven years of age who was the subject of Widespread Rheumatic Nodules on the Scalp, Arms, and elsewhere, and Rheumatic Periostitis of the Right Tibia, in whom there was no history or evidence of syphilis.

OBSTETRICAL SOCIETY OF LONDON.

Ectopic Pregnancy.—Notes on Cases and Exhibition of Specimens.

A meeting of this society was held at 20, Hanover-square, on Nov. 7th, Mr. **Alban Doran**, the President, being in the chair.

Dr. E. O. **Croft** read a paper on an Anomalous Case of Ectopic Pregnancy, probably Ovarian. The history and physical signs pointed to a diagnosis of some form of extra-uterine gestation, and the sac and its contents, found entire, were removed by abdominal section. There was free bleeding from rupture during the operation, and although it was soon controlled by ligature of the broad ligament the patient did not rally and died a few days afterwards. The necropsy revealed an absence of peritonitis and the pelvic organs were removed for further examination. The sac, before rupture, contained the complete ovum—a fœtus of about four months' growth, with placenta, membranes, and amniotic fluid. There was no blood or clot in the sac. Its relations were those of an ovarian tumour with short pedicle. The surface of the cyst contained follicles (? Graafian), and no separate structure corresponding to an ovary was evident on the same (right) side. The microscopical evidence of ovarian tissue in the wall was uncertain. The Fallopian tube was present and was uninjured; the fimbriated end was free and patent, and the layers of the mesosalpinx were undisturbed. The uterus was intact and the appendages on the opposite (left) side were normal. The possibility of the pregnancy being ovarian was suggested.

Dr. A. H N. **Lewers** then read a paper on a case of Repeated Ectopic Gestation in the same patient on whom laparotomy was performed on each occasion. The case was that of a patient, 29 years of age, who had been the subject of ectopic gestation on two occasions. There had been no uterine pregnancy. The first ectopic pregnancy occurred early in 1894. Laparotomy was performed in March, 1894, and the left Fallopian tube was removed, containing a tubal mole. This specimen was reported on by a committee of the Obstetrical Society of London.[1] The ostium of the tube was open but not dilated. The case on that occasion was one of threatened tubal abortion. In May, 1900—i.e., after an interval of a little more than six years—the patient was again the subject of ectopic gestation and laparotomy was again performed. The parts removed consisted of the right Fallopian tube and ovary and a tubal mole. The ostium of the tube was widely dilated and the mole had either been expelled into the peritoneal cavity or was lying loose in the dilated ostium at the time of the operation, so that on the second occasion the case was one of complete tubal abortion. The patient recovered well on both occasions. Reference was made to Dr. J. Haig Ferguson's paper on Repeated Ectopic Gestation in the same Patient[2] from which it appeared that, while there was a considerable number of cases reported of repeated tubal pregnancy in the same woman, laparotomy performed twice on the same woman was only mentioned in 14 cases. According to the same authority the interval between the ectopic pregnancies in the same patient has varied from six weeks to five years. In the case described by Dr. Lewers the interval, which was more than six years, seemed therefore to have been exceptionally long. Reference was also made to Dr. Edgar's paper on the same subject, published in the *Edinburgh Medical Journal* for 1899.

Dr. P. **Horrocks** thought that the specimen shown by Dr. Croft was well worthy of further examination and report by a sub-committee. He did not think that the fact that ovarian tissue was not found in all parts of the wall was proof that it was not an ovarian ectopic gestation. Neither could he see any *a priori* reason why an ovum should not become impregnated and develop whilst still in a Graafian follicle. Referring to Dr. Lewers's case Dr. Horrocks said that he had seen one or two instances of such repeated tubal gestations. He related a case in which he had removed a ruptured tubal gestation sac eight years ago and again six years ago. Dr. S B. Jolly of Sydenham had diagnosed the condition on the second occasion, but Dr. Horrocks rather doubted its probability owing to the extreme rarity of a repeated tubal gestation. The diagnosis was, however, confirmed by operation and verified by chorionic villi being microscopically proved to be present.

After some remarks by Dr. W. S. A. **Griffith**,

Mr. J. **Bland-Sutton** said that he could not satisfactorily discuss the question of ovarian pregnancy on a specimen in which the gestation had gone so far as it had in Dr. Croft's specimen. He would be convinced of ovarian pregnancy when he saw "an early embryo and its membranes contained in a sac in the ovary." This he considered a fair requisition and it corresponded with the facts on which the present not interpose that resistance to dilatation of the heart present in the healthy condition.—Dr. F. G. PENROSE referred to the work of *Dr. F. H. Poynton whose experience* was to the effect that myocarditis was generally present in cases of dilatation.—Dr. WILLIAM EWART remarked that the action of the cardiac valves and walls (as pointed out by Dr. Sansom) might suffer from fibrosis developing at the base of the heart, such as might result from pericarditis even when the latter did not lead to great effusion or adhesion. In a heart the valves of which were already damaged this additional influence might aggravate the valvular defect and explain the dilatation.—*Dr.* FISHER, in reply, stated that in his first case there had been a slight interstitial myocarditis. In his second case there was naked-eye evidence of recent degenerative changes, and Professor Stanley Kent had found in cultures from the heart muscle a diplococcus resembling that recently described by Dr. Poynton and Dr. A. Paine.

[1] Transactions of the Obstetrical Society of London, vol. xxxviii., p. 87.

[2] Edinburgh Medical Journal, 1899, p. 145.

Mr. R. CLEMENT LUCAS exhibited an Infant, six months old, in whom the Rectum Terminated in the Vagina. The anus was absent and there was no depression at its normal site. The rectum opened at the posterior part of the orifice of the vagina, between the hymen and the fourchette, by an aperture of about the size of a crow's quill. The deformity had passed unnoticed until the child was four months old. Mr. Lucas proposed, first, to establish a permanent anus in the normal position, and, later, to endeavour to close the vaginal aperture by a plastic operation.—Mr. ALFRED H. TUBBY had had a *similar case under his care at the Evelina* Hospital and had operated twice for the relief of the condition with a good result. His patient was a year old.

Dr. JAMES TAYLOR showed a lad, five years of age, affected with Mongolian Imbecility. The patient had a short head, somewhat compressed antero-posteriorly, epicanthal folds, and the mental peculiarities usually associated with this condition. His temper was good. The limbs and little fingers were free from deformity. The child, however, showed a curious power of over-extension of the fingers (and, indeed, of all the joints). There was a suspicion of congenital syphilis.—Dr. FLETCHER BEACH said that in his experience syphilis accounted for only 1 per cent. of these cases. He pointed out that thyroid extract was useless in Mongolian imbecility.—Dr. G. E. SHUTTLEWORTH stated that about 5 per cent of the children at the Royal Albert Asylum were Mongolian imbeciles. He had found deformity of the little finger common in many of the children of Mongol type presented for admission to the special schools of the London School Board. He was inclined to consider that a Mongol represented permanently a fœtal stage of development—*in other words, that such a child came into the world unfinished, and remained so, more or less,* all his or her life. Some 40 per cent. of such children were found to be the youngest members of large families, and anything that depressed the procreative powers of the mother might conceivably be a factor in the production of the cases.—Dr. TAYLOR, in reply, said that with regard to syphilis Dr. G. E. Sutherland in 25 Mongols had ascertained that syphilis was present in 11. He thought that Mongols were not uncommonly the first-born and not the last-born of a family.

Mr. TUBBY showed a child, aged three months, with Cephalhæmatoma over the Right Parietal Bone. The labour had not been protracted, the presentation was vertical, and *forceps* had not been used. The swelling, which had gradually become larger, was not noticed until a day or two after birth. The tumour was not hot or tender or red; its margin was crateriform and hard where it merged with the skull.

Mr. TUBBY also exhibited a girl, aged six years, suffering from a Congenital Anterior Dislocation of the Right Hip *and showed some radiograms The summit of the great* trochanter lay an inch above Nélaton's line and the head of the femur could be felt lying posteriorly to the anterior superior iliac spine. An attempt had been made to remedy the condition by forcible movements after dividing the tendons of the adductors, sartorius, and the tensor vaginæ femoris, but the deformity had recurred.—Mr. J. JACKSON CLARKE, in connexion with this case, brought forward several interesting skiagrams. One of his patients, a girl, aged two years, had been treated by the method adopted by Mr. Tubby and was now practically cured. He agreed with Mr. Tubby in thinking that up to the age of about four years these cases could be cured by operation.

Mr. SYDNEY STEPHENSON showed a case of early Myxœdema associated with Ectropion in a girl, 12 years of age. The skin over the cheeks, nose, upper lip, and eyelids was pinkish and swollen, so that the lines of expression were obliterated, especially on the left side of the face. The swelling was firm and did not pit on pressure. Around the eyelids the skin was rough, dry, and covered with fine, branny scales. There was no general œdema of the body. The *hands and feet were somewhat "podgy."* The nails were brittle. Speech and movements were slow and deliberate. The lower lids and corresponding puncta lacrymalia were slightly averted. The upper lids were congenitally short. The isthmus of the thyroid gland could be felt. There were no supra clavicular pads. The urine was free from albumin. The temperature was 98·2° F., the respirations were 19, and the pulse was 80. The child was sensitive to cold.—Dr. PERCY G. LEWIS, in connexion with this case, showed photographs and gave details of myxœdema in young subjects.—Dr. FISHER recalled a case of intermittent albuminuria which appeared much like this.—Mr. STEPHENSON, in reply, said that the urine had been examined seven or eight times, but albumin had never been found. The character of the œdema, the slowness of the speech, and the "stodginess" of the hands appeared to militate against the case being one of intermittent albuminuria, as suggested by *Dr. Fisher.*

Dr. G. E. SUTHERLAND showed an instance of Extreme Adiposity in an infant, aged eight months, who weighed 29½ lb. The child had been fed exclusively upon the breast. *The general health had been good, there had* been no gastro-intestinal disturbances, and, although extremely fat, the infant could sit up and move her limbs actively. There was no family history of lipomatosis, but two other children had also been stout as infants. In this case the fat was diffused generally over the body and extremities. There was slight rachitis. Examination of the maternal milk showed the presence of 8·2 per cent. lactose and of 0·44 per cent. proteids, the other constituents being normal.—*Dr.* SANSOM *observed that the child had a* placid, healthy expression, and he thought that there was no adiposis neurotica. It was remarkable that the milk included so large a proportion of lactose, an observation that he supposed had been confirmed by repeated analyses.—Dr. EDMUND CAUTLEY inquired whether the infant had been given anything besides mother's milk. He had seen an infant who weighed 27½ lb. at the age of six months, but the parents had been in the habit of giving articles of food other than breast milk.—Dr. WAYLAND C. CHAFFEY regarded the case as one not of lipomatosis but of simple increase of fat.—Dr. SUTHERLAND, in reply, *said that he thought the child did not suffer from* lipomatosis, at least in the pathological sense. Four ounces of the breast milk, drawn off in the morning, had been analysed by Mr. Pakes of Guy's Hospital. Dr. Sutherland was satisfied from his inquiries that the child had had no food other than breast milk.

Dr. J. H. SEQUEIRA showed a case of Polyuria in a child, aged three years. Excessive thirst and increased frequency of micturition had been noticed *since the age of eight months* following an attack of whooping-cough. There was no history of injury. On coming under Dr. Sequeira's care the child weighed 16¼ lb., the skin was dry and pale, and there was evidence of rickets. The temperature was normal; there were no signs of disease of the abdominal or thoracic organs. The pale urine had a specific gravity of 1010 and an alkaline reaction. It contained albumin (at times reaching 1 per cent.), but no deposit or casts. The quantity of urine averaged 36 ounces a day and once it reached as much as 47 ounces. The child had lost a pound and a quarter in weight in the five months during which he had been under Dr. Sequeira's observation. The condition *appeared to depend* upon a chronic dilatation of the renal arteries and as such would probably be classed as one of diabetes insipidus, although the constant alkalinity of the urine and the occasional presence of albumin were held to militate against this view. Dr. Sequeira found that the urine could be rendered temporarily acid by the administration of the acid phosphate *of sodium* in five-grain doses three *times a day, as advised by Dr. Robert* Hutchison.—Dr. SANSOM, who endorsed the diagnosis, regarded the case as a very valuable one.—Dr. LEWIS had been working at an allied subject—namely, bed-wetting in children, which he believed to be due to polyuria and to be associated with the indigestion of starchy foods. It could be stopped at once by an anti-diabetic defective.—Mr. JOHN GRIFFITH expressed his strong opinion that the disease was a congenital and not an infantile one, referring it to defective development of enamel cells in the sixteenth week of fœtal life rather than to anomalous calcification.—Mr. BENNETT briefly replied, and in answer to the President's question he stated that he had not carefully investigated the family history.

The following cases and card specimens were shown:—

Mr. SIMEON SNELL: Epithelioma of the Cornea. The patient was a soldier aged 45 years, with a history of injury seven years ago. In May, 1898, the growth was removed, but it recurred. Mr. Snell first saw the patient in August, 1900, when the growth filled the inter-palbebral space. The eyeball was enucleated, and the growth was shown to be an epithelioma.

Mr. JOHN GRIFFITH: A specimen of Osteo-sarcoma of the Orbit.

Mr. TREACHER COLLINS and Mr. A. VERNON FORD: A case of Bullet Wound of the Orbit followed by Blindness of Both Eyes. The patient was with Admiral Sir E. H. Seymour's expedition for the relief of Pekin. He was shot through the head with a bullet, and it was found that in one eye the choroid was ruptured while in the other the retina was detached.

Mr. A. W. ORMOND: A Chancre of the Upper Lid at the Retrotarsal Fold.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Salpingo-oöphorectomy.—Some New Methods in Pelvic Operations on the Female.

A MEETING of this society was held on Nov. 8th, Dr. H. MACNAUGHTON-JONES being in the chair.

The following specimens were shown:—

Dr. R. T. SMITH: A case of Degenerating Fibro-myoma.

Mr. CHARLES RYALL: A case of Hysterectomy for Fibromyoma.

Dr. MACNAUGHTON-JONES: (1) A case of Hysterectomy for Fibro-myoma; and (2) a case of Broad Ligament Cyst.

In the discussion on these specimens the following speakers took part: Dr. HEYWOOD SMITH, Dr. HERBERT SNOW, Dr. ARTHUR GILES, Dr. J. J. MACAN, and Mr. RUTHERFORD MORISON.

Dr. MACNAUGHTON-JONES read a short communication on a case of Salpingo-oöphorectomy.

Mr. RUTHERFORD MORISON (Newcastle-on-Tyne) read a paper and gave a lantern demonstration on Some New Methods in Pelvic Operations on the Female. The operations considered were as follows. 1. Abdominal resection of the sigmoid or upper portion of the rectum. This operation was intended for cases in which suppuration of the left uterine appendages involved the bowel to such an extent as to demand its removal or in which the abdomen was opened for a cancerous growth of the sigmoid in mistaken diagnosis for a diseased and enlarged ovary. The steps of the operation were: (1) the diseased bowel was excised; (2) a glass bobbin, with indiarubber tube attached, was tied tightly into the upper end of the sigmoid flexure; (3) the indiarubber tube was passed down from above through the lower cut and into the rectum, where it was aided to pass through the anus by the finger of an assistant; (4) the tube was drawn upon till the ligature on the upper cut end of the bowel was inside of the lower cut end of the bowel; (5) a ligature was then passed round immediately below the lower cut end and tightly tied (this made the junction watertight); and (6) the tube was again pulled upon, whilst the lower portion of the bowel immediately below the button was steadied till by traction from above a short intussusception was produced. This was maintained by a few Lembert's sutures. In from four to eight days the ligatured sloughing bowel separated and the tube was thus released. He had done this operation 14 times—in two cases for complicated pyosalpinx and in 12 for malignant disease. Seven patients died. The percentage mortality was therefore high but might be diminished by avoiding the mistake he had made of performing this operation in cases of obstruction with loaded colon, for experience had taught him that in these cases the colon should be emptied by a preliminary colotomy before a radical operation was attempted. 2. An operation for certain forms of parametric abscess. Mr. Morison divided cases of pelvic cellulitis into three classes: (1) the floor of the broad ligament was involved—the abscess pointed towards the vagina; (2) the cellular tissue of the broad ligament between its peritoneal folds was invaded—the abscess pointed above Poupart's ligament; and (3) the lymphatic vessels and glands alongside the iliac vessels were affected and the abscess was found high up on the back wall of the pelvis or in relation to the psoas and iliacus muscles. In the third form the pus was out of reach from the vagina and having had two fatal cases in which he evacuated the pus by opening the abdomen he devised the following plan. The abdomen was opened by an incision three or four inches long made in the middle third of a line drawn from the centre of the back of the ilio-costal space behind to one inch above the symphysis in front. Through this incision the diagnosis was confirmed by palpation of the uterus, ovaries, and tubes, and the relations of the abscess were ascertained. The incision was next prolonged to the back of the ilio-costal space, through the oblique and transversalis muscles, leaving the transversalis fascia and peritoneum intact. The peritoneum and fascia were then held forward with forceps and with the left hand in the abdomen as a guide the index finger of the right hand introduced posteriorly opened the abscess by bluntly perforating the transversalis fascia under the thickest part of the swelling. A drainage-tube and iodoform gauze packing round it completed this part of the operation. Twenty cases operated on by this method had all recovered. 3. The control of the uterine arteries in abdominal hysterectomy. Since completing his notes he had found that his plan was neither new nor peculiar to himself. The special point about it was that the uterine arteries were seized with forceps and the uterus was cut away before the vessels were ligatured. 4. Operation for incontinence of urine in the female. In a case of incontinence with a patulous urethra he performed the following operation. An incision one inch long was made in the middle line of the abdomen midway between the umbilicus and the symphysis down to the peritoneum. The patient was then placed in the lithotomy position and a circular incision was made round the orifice of the urethra. A second incision was made through the anterior vaginal wall along the course of the urethra and for one inch on to the base of the bladder. The urethra and neck of the bladder were then entirely separated. A pair of closed hæmostatic forceps was next passed down from the opening above the pubes close to the pubic symphysis and into the vagina; the end of the urethra was caught in the forceps, drawn upwards, and attached to the skin of the incision in the abdominal wall. The remainder of the incision was closed round the urethra and an indiarubber catheter was tied in the bladder and projected from the anterior abdominal wall. On the seventh day the dressings were dry and the wound was healed. He had only hoped to make a continent bladder which could be readily emptied by the catheter, but more had been gained, for the bladder would now hold one and a half pints of urine against every effort to make it leak, such as coughing, straining, and alterations in posture; and when the patient was in good form she could easily and entirely empty it by voluntary effort.

In the discussion on the paper the following speakers took part: Dr. SNOW, Mr. SKENE KEITH, Dr. P. Z. HEBERT, Dr. WILLIAM TRAVERS, Dr. HEYWOOD SMITH, Dr. E. A. NEATBY, Mr. RYALL, Dr. R. H. HODGSON, Dr. GILES, and Dr. MACNAUGHTON-JONES; and Mr. RUTHERFORD MORISON replied.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Oct. 19th, Dr. A. ERNEST SANSOM being in the chair.

Dr. THEODORE FISHER showed a specimen of Rheumatic Dilatation of the Heart from a patient who died from cardiac failure one year after an attack of acute rheumatism. The heart was hypertrophied as well as dilated and weighed 19½ ounces. The valves were healthy and the pericardium was adherent only over a small area, about two inches square, near the apex of the left ventricle. Dr. Fisher mentioned another case in a child, 11 years of age, with rheumatic nodules, where there was an almost entire absence of valvular disease. The heart was found to weigh 11¼ ounces.—Dr. J. H. SEQUEIRA discussed the *rôle* played by the pericardium in such cases and pointed out that an inflamed and softened pericardium could not interpose that resistance to dilatation of the heart present in the healthy condition.—Dr. F. G. PENROSE referred to the work of Dr. F. H. Poynton whose experience was to the effect that myocarditis was generally present in cases of dilatation.—Dr. WILLIAM EWART remarked that the action of the cardiac valves and walls (as pointed out by Dr. Sansom) might suffer from fibrosis developing at the base of the heart, such as might result from pericarditis even when the latter did not lead to great effusion or adhesion. In a heart the valves of which were already damaged this additional influence might aggravate the valvular defect and explain the dilatation.—Dr. FISHER, in reply, stated that in his first case there had been a slight interstitial myocarditis. In his second case there was naked-eye evidence of recent degenerative changes, and Professor Stanley Kent had found in cultures from the heart muscle a diplococcus resembling that recently described by Dr. Poynton and Dr. A. Paine.

Mr. R. CLEMENT LUCAS exhibited an infant, six months old, in whom the Rectum Terminated in the Vagina. The anus was absent and there was no depression at its normal site. The rectum opened at the posterior part of the orifice of the vagina, between the hymen and the fourchette, by an aperture of about the size of a crow's quill. The deformity had passed unnoticed until the child was four months old. Mr. Lucas proposed, first, to establish a permanent anus in the normal position, and, later, to endeavour to close the vaginal aperture by a plastic operation.—Mr. ALFRED H. TUBBY had had a similar case under his care at the Evelina Hospital and had operated twice for the relief of the condition with a good result. His patient was a year old.

Dr. JAMES TAYLOR showed a lad, five years of age, affected with Mongolian Imbecility. The patient had a short head, somewhat compressed antero-posteriorly, epicanthal folds, and the mental peculiarities usually associated with this condition. His temper was good. The limbs and little fingers were free from deformity. The child, however, showed a curious power of over-extension of the fingers (and, indeed, of all the joints). There was a suspicion of congenital syphilis.—Dr. FLETCHER BEACH said that in his experience syphilis accounted for only 1 per cent. of these cases. He pointed out that thyroid extract was useless in Mongolian imbecility.—Dr. G. E. SHUTTLEWORTH stated that about 5 per cent. of the children at the Royal Albert Asylum were Mongolian imbeciles. He had found deformity of the little finger common in many of the children of Mongol type presented for admission to the special schools of the London School Board. He was inclined to consider that a Mongol represented permanently a fœtal stage of development—in other words, that such a child came into the world unfinished, and remained so, more or less, all his or her life. Some 40 per cent. of such children were found to be the youngest members of large families, and anything that depressed the procreative powers of the mother might conceivably be a factor in the production of the cases.—Dr. TAYLOR, in reply, said that with regard to syphilis Dr. G. E. Sutherland in 25 Mongols had ascertained that syphilis was present in 11. He thought that Mongols were not uncommonly the first-born and not the last-born of a family.

Mr. TUBBY showed a child, aged three months, with Cephalhæmatoma over the Right Parietal Bone. The labour had not been protracted, the presentation was vertical, and forceps had not been used. The swelling, which had gradually become larger, was not noticed until a day or two after birth. The tumour was not hot or tender or red; its margin was crateriform and hard where it merged with the skull.

Mr. TUBBY also exhibited a girl, aged six years, suffering from a Congenital Anterior Dislocation of the Right Hip and showed some radiograms. The summit of the great trochanter lay an inch above Nélaton's line and the head of the femur could be felt lying posteriorly to the anterior superior iliac spine. An attempt had been made to remedy the condition by forcible movements after dividing the tendons of the adductors, sartorius, and the tensor vaginæ femoris, but the deformity had recurred.—Mr. J. JACKSON CLARKE, in connexion with this case, brought forward several interesting skiagrams. One of his patients, a girl, aged two years, had been treated by the method adopted by Mr. Tubby and was now practically cured. He agreed with Mr. Tubby in thinking that up to the age of about four years these cases could be cured by operation.

Mr. SYDNEY STEPHENSON showed a case of early Myxœdema associated with Ectropion in a girl, 12 years of age. The skin over the cheeks, nose, upper lip, and eyelids was pinkish and swollen, so that the lines of expression were obliterated, especially on the left side of the face. The swelling was firm and did not pit on pressure. Around the eyelids the skin was rough, dry, and covered with fine, branny scales. There was no general œdema of the body. The hands and feet were somewhat "pudgy." The nails were brittle. Speech and movements were slow and deliberate. The lower lids and corresponding puncta lacrymalia were slightly averted. The upper lids were congenitally short. The isthmus of the thyroid gland could be felt. There were no supra-clavicular pads. The urine was free from albumin. The temperature was 98·2° F., the respirations were 19, and the pulse was 80. The child was sensitive to cold.—Dr. PERCY G. LEWIS, in connexion with this case, showed photographs and gave details of myxœdema in young subjects.—Dr. FISHER recalled a case of intermittent albuminuria which appeared much like this.—Mr. STEPHENSON, in reply, said that the urine had been examined seven or eight times, but albumin had never been found. The character of the œdema, the slowness of the speech, and the "stodginess" of the hands appeared to militate against the case being one of intermittent albuminuria, as suggested by Dr. Fisher.

Dr. G. E. SUTHERLAND showed an instance of Extreme Adiposity in an infant, aged eight months, who weighed 29½ lb. The child had been fed exclusively upon the breast. The general health had been good, there had been no gastro-intestinal disturbances, and, although extremely fat, the infant could sit up and move her limbs actively. There was no family history of lipomatosis, but two other children had also been stout as infants. In this case the fat was diffused generally over the body and extremities. There was slight rachitis. Examination of the maternal milk showed the presence of 8·2 per cent. lactose and of 0·44 per cent. proteids, the other constituents being normal.—Dr. SANSOM observed that the child had a placid, healthy expression, and he thought that there was no adiposis neurotica. It was remarkable that the milk included so large a proportion of lactose, an observation that he supposed had been confirmed by repeated analyses.—Dr. EDMUND CAUTLEY inquired whether the infant had been given anything besides mother's milk. He had seen an infant who weighed 27½ lb. at the age of six months, but the parents had been in the habit of giving articles of food other than breast milk.—Dr. WAYLAND C. CHAFFEY regarded the case as one not of lipomatosis but of simple increase of fat.—Dr. SUTHERLAND, in reply, said that he thought the child did not suffer from lipomatosis, at least in the pathological sense. Four ounces of the breast milk, drawn off in the morning, had been analysed by Mr. Pakes of Guy's Hospital. Dr. Sutherland was satisfied from his inquiries that the child had had no food other than breast milk.

Dr. J. H. SEQUEIRA showed a case of Polyuria in a child, aged three years. Excessive thirst and increased frequency of micturition had been noticed since the age of eight months following an attack of whooping-cough. There was no history of injury. On coming under Dr. Sequeira's care the child weighed 16½ lb., the skin was dry and pale, and there was evidence of rickets. The temperature was normal; there were no signs of disease of the abdominal or thoracic organs. The pale urine had a specific gravity of 1010 and an alkaline reaction. It contained albumin (at times reaching 1 per cent.), but no deposit or casts. The quantity of urine averaged 30 ounces a day and once it reached as much as 47 ounces. The child had lost a pound and a quarter in weight in the five months during which he had been under Dr. Sequeira's observation. The condition appeared to depend upon a chronic dilatation of the renal arteries and as such would probably be classed as one of diabetes insipidus, although the constant alkalinity of the urine and the occasional presence of albumin were held to militate against this view. Dr. Sequeira found that the urine could be rendered temporarily acid by the administration of the acid phosphate of sodium in five-grain doses three times a day, as advised by Dr. Robert Hutchison.—Dr. SANSOM who endorsed the diagnosis, regarded the case as a very valuable one.—Dr. LEWIS had been working at an allied subject—namely, bed-wetting in children, which he believed to be due to polyuria and to be associated with the indigestion of starchy foods. It could be stopped at once by an anti-diabetic diet. He did not deem it necessary to limit the amount of liquid taken. Dr. Lewis regarded the present case as belonging to that category.

Dr. George Carpenter showed a case of typical Epiphysitis in a child, seven weeks old. The family history suggested syphilis. The child was anæmic and "snuffled" loudly. Both upper extremities were affected. The cutaneous manifestations present were not characteristic. An x-ray photograph failed to demonstrate the obvious changes at the epiphyses.

LIVERPOOL MEDICAL INSTITUTION.

Unusual Form of Rodent Ulcer.—Dermatitis Herpetiformis.—Pulmonary Tuberculosis.—Disease among Natives in Nyassaland.

The third meeting of the session of this society was held on Nov. 8th, Dr. A. Bernard, the senior Vice-President, being in the chair.

Mr. F. T. Paul showed a patient suffering from an Unusual Form of Rodent Ulcer and said that it was unlike anything he had ever seen before. It was a very large tumour of the left side of the face, measuring five and a half inches across and from two to three inches in thickness, and had the structure of the glandular type of rodent ulcer. There were no secondary deposits. The patient was a man, aged 43 years. At 19 years of age he knocked the skin off the cheek below the eye; this never properly healed and at 32 years of age the late Mr. H. O. Thomas excised a small sore; at 34 years of age he was operated on by Mr. Robert Jones; and at 35 years of age by Mr. Paul who examined the growth and pronounced it rodent ulcer. It returned within a year and had been growing since to its present dimensions. Mr. Paul considered all forms of so-called rodent ulcer to be varieties of carcinoma of the appendages of the skin. The ordinary form was carcinoma of the sebaceous glands, but cases like the present probably originated in the sweat glands.—Mr. Rushton Parker remarked that any difficulties of nomenclature alluded to by Mr. Paul probably arose from the use of the term "rodent ulcer" in the British Islands and abroad the terms "carcinoma," "haut-krebs," or "skin cancer" were used for the same class of cases, irrespectively of variety. He considered Mr. Paul's case to be an ulcerated carcinoma of the skin of the face but not "rodent" in a physical sense, as there was a gain rather than a loss of substance; but its histological characters were obviously a variety of what was known as "rodent carcinoma."

Dr. J. Stopford Taylor read notes of a case of Dermatitis Herpetiformis Multiformis in a man, aged 66 years, which ran an acute course in about 14 days, and when hopes of recovery were entertained pneumonia supervened and death resulted. An unusual and unprecedented symptom was the great quantity of serum which exuded from the erythema-multiforma-like type of the eruption situated upon the back and buttocks. This condition was rightly described as a chronic disorder, yet this was his second acute case followed by a fatal termination.—Dr. F. H. Barendt considered that the pneumonia was incidental and not a consequence of the skin lesions. He alluded to herpes gestationis which clinically was the same disease occurring in pregnancy. The etiology was still obscure; probably it would be cleared up when their knowledge of toxins became more exact and definite.—Dr. R. J. M. Buchanan referred to two cases; in one the herpetic eruption resembled confluent small-pox, but the association of croupous pneumonia cleared up the uncertainty of diagnosis; in the other the herpetic eruption appeared after the acute pneumonia was advanced and the pneumococcus was present in the exudation from the vesicles.—Dr. Stanley A. Gill called attention to the connexion there seemed to be between skin and pulmonary diseases and cited a case in which a patient when cured of eczema suffered from asthma which was only relieved by the reappearance of the eczema.

Dr. Buchanan read notes on cases of Pulmonary Tuberculosis in reference to the probable origin of the invasion. In many cases the tuberculous history was definitely referred to an attack of so-called influenza. He offered the suggestion that many of the so-called sporadic attacks of influenza were probably the expression of the initial infection with the tubercle bacillus and that special attention should be given to the diagnosis of tuberculosis in its primary invasion. Dr. Buchanan related three cases of pulmonary tuberculosis in which he had traced the source of infection. The cases, previously healthy, were infected in offices where clerks suffering from consumption had been employed. He had been able to persuade the employer in one of the cases to have his offices disinfected and the office books stoved.—Dr. A. G. Gullan cited a case under his care where he had been able to trace a definite source of infection. He considered the stage of convalescence following true influenza, which was always associated with great debility, very liable to the infection of tuberculosis.—Dr. C. J. Macalister directed attention to the fact that a number of seamen suffered from phthisis notwithstanding their open-air life and he advocated care in regard to cleanliness and ventilation of their quarters.

Mr. J. S Kellett Smith read a paper upon Disease among the Natives of the Nyassaland Plateau, compiled from notes in his medical diary kept during the exploration of the country in the years 1895–96. Anthropometrical statistics of various tribes were given and the general physical development of the native was described. Points of interest brought forward were the existence of tetanus and rabies, the absence of deformities, and the question of hernia. Umbilical herniæ were shown to be very frequent and to disappear spontaneously during the earlier years of life. Inguinal herniæ were practically unknown and Mr. Smith thought that this was accounted for chiefly by the position in which the newly-born infant was nursed, with the legs embracing the mother's flank and the inguinal regions supported by the conforming pressure of the mother's side, and in later life by the posture adopted by the native when disposing himself to the necessary eliminating function. Syphilis seemed to be incapable of permanence among the natives of this country. All scars tended to become keloid, but the keloids never took on malignant tendency. Especially was it notable that in this primitive part of Africa malignant tumours, whether of epithelium or connective tissue, seemed to occur so rarely as to be practically unknown.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Undescended Testicle, Congenitally Misplaced Testicle, and Congenital Deficiency of Testicle.—Multiple Tumours of Unusual Type.—Exhibition of Cases and Specimens.—Election of Office-bearers.

The first ordinary meeting of the eightieth session of this society was held on Nov. 7th, Dr. A. G. Miller, the President, being in the chair.

Professor T. Annandale read a paper on the Operations for Undescended Testicle and for Congenitally Misplaced Testicle, with a Note of a Rare Form of Congenital Deficiency of the Testicle. He stated that the condition of misplaced testicle was not common: The testicle might, however, be situated (1) on one side of the perineum; (2) in front of the pubes at the root of the penis; or (3) in the region of the saphenous opening. In any situation it might become very troublesome on account of inflammation or if associated with a hernia. The testicle underwent degeneration when it was not in the scrotum, and it thus became functionless when it was retained in the abdomen or in the inguinal canal. Mr. Joseph Griffiths's experiments with the testicle in dogs in this connexion were narrated briefly. In the *British Medical Journal* of Jan. 4th, 1879, Professor Annandale described a case in which he had successfully removed the testicle from the perineum and replaced it in the scrotum in a child aged three years. The important details of the operation were: firstly, the incision, then the careful exploration of the spermatic cord; the drawing out of the cord and testicle and the division of all attachments; the opening up of the scrotum, placing the testicle there, and fixing it by catgut sutures. If the cord were too short it might be lengthened by careful traction and division of the cremasteric fibres. The operation should be performed in early childhood. In the case of undescended testicle much trouble might arise from inflammation or involvement in a hernial sac. In the child attempts to bring it down into the scrotum should be made first. Usually such testicles were small and atrophied, yet a chance to develop should be afforded them by replacing them in the scrotum. If one testicle were already in the scrotum there was no such great indication for replacing the other one. In the case of adults Professor Annandale invariably removed such undescended testicles when he had to operate for hernia. In young persons an attempt to replace the testicle and to keep it down by steady traction by catgut stitches should be made. Congenital deficiency of the testicle was comparatively rare, but two cases had lately come under his observation. In the first case the patient was a youth, aged 18 years. The left side of the scrotum was small and at the upper part of it a soft body was felt, but this possessed no testicular sensation. An incision was made over this, exposing the cord and sac. The cord was found to be natural and it ended in this soft body. Both were removed. The other case was almost exactly similar, but it occurred in a man, aged 26 years. The specimens removed showed that the vas deferens was well developed and passed down to the lower part of the soft body ending in a closed extremity. There was no trace of testicular substance. The body in both cases consisted merely of convoluted vas deferens surrounded by a dense envelope. In such rare cases operation might be justifiable in order to relieve mental or local disturbance.—Professor J. CHIENE drew attention to the priority of Professor Annandale's operations for misplaced testicle. He usually classed undescended testicle into three groups: (1) those in the abdomen; (2) those in the canal; and (3) those in a double condition. Where the testicle was in the abdomen he thought it best to leave it; if it were in the canal in children to apply a U-shaped truss in order to try and push it down; and if at puberty to remove it.—Mr. HAROLD J. STILES stated that all undescended testicles might be excised, as in every one which he had examined there was an entire absence of testicular substance.—Mr. SHAW McLAREN, Dr. WHITE BALLANTYNE, and Dr. THEODORE SHENNAN made some remarks and Professor ANNANDALE replied.

Mr. J. M. COTTERILL and Dr. D. A. WELSH contributed a short note on a case of Multiple Tumours of Unusual Type (with exhibition of patient, specimens, and lantern demonstration). The patient, a man, aged 24 years, had been under observation for more than five years suffering from multiple superficial tumours. Many medical men had seen the case, but no definite opinion had been arrived at. The previous history of the patient was perfectly good, as was also his family history. In 1893, when at work as a joiner, the patient fell a distance of 22 feet and injured his right wrist. He soon recovered, but four months later a small red painless point appeared at the back of the right wrist. He attended regularly twice a week at a hospital in Glasgow. The disease was there called a "gumma." The ulcer did not, however, improve, though it was scraped and cauterised. Erysipelas supervened and the hand became drawn to the ulnar side. The ulcer became larger, irregular, and eroded more deeply, exposing the lower end of the ulna. Sedatives were applied to the ulcer and tonics were administered internally. He was treated at the Edinburgh Infirmary by iodide of potassium in doses of from 10 to 20 grains thrice daily along with mercury. The patient left the hospital and returned in some months' time to have the arm amputated as there was a secondary growth in the epitrochlear gland. The arm was therefore removed above the elbow-joint in December, 1896. Two years later the patient returned with a small pimple on the forehead and a growth on the outer side of the left elbow. The ulcer on the forehead was tender and grew larger, though it was treated. Eventually it was excised, as was also a lump over the deltoid muscle. After another interval of two years he returned on July 4th, 1900, with a growth on the right great toe on the site of an ingrowing toe-nail. There was also a similar growth on the left great toe and another on the second left toe. There were also other ulcers present over the body—e.g., on the nates, on the top of the head, in the scar on the deltoid, &c. All these were removed, including the toes themselves. As regards the views which had been held respecting this case Mr. Cotterill said that with regard to tuberculosis the ulcers had never had the characteristic appearance and there had been no undermining of the edges or secondary glandular infection. As to epithelioma the age of the patient was against that view, as was also the fact of the healing of the ulcers. The absence of glandular involvement and the unusual sites also militated against that diagnosis. As regarded syphilis, the growths had not a gummatous appearance nor had the ulcers had any of the characteristic chamois-leather sloughs; the glands had remained unaffected, and in spite of treatment by iodides and mercury the disease had progressed. The chronicity of the course and the facts of the healing and the absence of internal manifestations almost negatived the idea of sarcoma. As to rodent ulcer the position was extraordinary and every tissue on which the ulcers were situated was eaten away. As to the diagnosis of chronic farcy there was no initial acute attack or any nasal trouble. The patient's mode of life hardly exposed him to such infection and the duration of the disease (seven years) was far beyond the average. Inoculation of guinea-pigs with virus from the patient gave negative results. Mycosis fungoides appeared to be precluded, as there was no fungation in this case but merely erosion.—Dr. WELSH exhibited lantern slides in illustration of this case and stated that, pathologically considered, epithelioma might be dismissed, as also rodent ulcer, for in this case the epithelial structures of the skin were not involved. There were great variations in the structure of the nodules from different areas and so the growths partook more of the nature of the chronic granulomata. Organisms were sought for but none were found.—Professor ANNANDALE thought that the case looked like one of recurrent fibroid tumours which were very liable to degenerate.—Mr. F. M. CAIRD thought that it was closely allied to syphilis and said that some abnormal cases of syphilis did not react to iodide of potassium or mercury.—Dr. NORMAN WALKER gave reasons for thinking that it was a case of rodent ulcer, while Mr. STILES thought it was not in the least like rodent ulcer.

The following cases and specimens were shown:—

Dr. ALLAN JAMIESON showed: 1. A case of Acne Keloid. The patient was a woman, aged 40 years, who had been under treatment seven years previously for boils on the back of the neck. She remained well until about three years ago when these boils reappeared and continued to do so for about 18 months. At the end of this time a small tumour of half the size of a marble formed at the centre of the neck. This underwent progressive enlargement and especially since the birth of the patient's last child. The tumour was now a large dense hard body lying across the back of the neck, freely moveable, and fairly smooth on the surface. It presented numerous apertures, from each of which a brush-like arrangement of hairs protruded. The patient experienced some relief when these hairs were pulled out, and on firm squeezing pus could be expelled from these apertures. The case was one of acne keloid, the fibrous tissue being developed from the former pustules. Its situation was classical. Unna found fault with the name because no comedones were present in this disease. The name might not be etiologically correct and "pustulo-keloid" might be the best name to give it. The keloid developed in the acne scars and lately Dr. Jamieson had seen a young man who had several hundreds of small keloid growths on his back and chest, arranged obliquely from above downwards and outwards. As regards treatment electrolysis might be employed, but no local applications seemed to have much effect. 2. A case of Tylosis Palmæ. In this case the disease could be distinctly traced back for five generations and possibly it extended still further back. The patient was a boy, aged five years. At birth it was noticed that he had a peculiar yellowish semi-translucent thickening of the skin of the palms. At present the lines of flexion were well marked and the thickening covered the entire palms and the same was present on the feet. Sensation over the areas affected was interfered with. There were two other children in the same family, but they were quite healthy. The patient's mother and the other members of the family were similarly affected, as were also the grandmother and seven among the brothers and sisters, and the great-grandmother and some of her family as well, as the great-great grandmother. The disease had chiefly affected the female line. It was related to ichthyosis, if it were not indeed a form of that condition, and it was due to the persistence of the fœtal epitrichium which had not been thrown off after birth. No treatment (as by salicylic acid, &c.) had had any permanent effect, as the skin grew just as thickly afterwards. The mother found it best merely to rub the thickened skin down with pumice stone. 3. A Case for Diagnosis. The patient was a woman, aged 36 years. There were three growths on the upper part of the left side of the chest; they first appeared about three months ago. One of these growths was large and pink and covered by vascular ramifications. The growth was purely in the skin and the axillary glands were not enlarged. The skin between the growths was atrophied and scar-like, though this was not due to previous growths. In all probability it was an epithelioma of the skin.

Dr. G. A. GIBSON showed two cases of Friedreich's

Ataxia. There were five in the family and three members of it suffered from this disease. The patients shown were two brothers, aged 26 years and 21 years respectively. In the eldest the disease began while at school, the first symptom being difficulty in walking. At present he had a complete loss of the cutaneous and tendon reflexes; there was an entire absence of sensory disturbance; the action of the muscles of the whole body was weak, and there was well-marked nystagmus. The same conditions were present in the younger brother, but in his case some of the cutaneous reflexes were retained. In both the characteristic symptoms—e.g., slurring of the words in reading and great tremulousness on attempting voluntary motion—were present. The gait in neither was typically ataxic but it was unsteady, with reeling at times. There was almost no impairment in the field of vision and the Argyll-Robertson phenomenon was not present.

Dr. H. G. Langwill exhibited a youth, aged nearly 19 years, who suffered from Regurgitation of Food after Eating. The lad was quite undeveloped physically and appeared to be not older than about 13 years. He was apparently healthy until three years ago, when he began to complain of pain after eating, and this ended in sickness usually within a quarter of an hour. If he did not vomit then the pain lasted for about an hour. There had never been hæmatemesis or melæna. He could retain fish and light food with greater ease. About a year ago along with the pain after eating he began to suffer from regurgitation of food. He could not eat sufficient food to appease his appetite and was consequently always hungry. The pain had not been so severe during the past year, but he had always complained of weight and swelling over the stomach. At present he could only take food in small amounts and he required a long time in which to masticate and to swallow it—as, for example, for breakfast he ate only half a slice of bread and a small cupful of milk and took an hour in which to eat this. The fluid which was regurgitated was always from two to three ounces in amount, alkaline or neutral in reaction, and had never contained hydrochloric acid. He had not grown since the age of 13 years and now he weighed only 3 st. 8½lb. (two years ago his weight was 5½ st.). Physically nothing wrong could be detected excepting enlargement of the submaxillary glands. On feeding him with the stomach tube not more than two or three ounces could be injected, any excess being regurgitated alongside of the tube.

Dr. Byrom Bramwell showed a rare case of Pre-ataxic Tabes. The patient was a man, aged 33 years, who had suffered much from frequently recurring gastric crises. These attacks of vomiting began four years ago and occurred usually at intervals of six weeks. Each attack might last 10 days. During these he had no pain but could retain nothing on the stomach. He had no dyspeptic troubles other than these. At first the vomit consisted of food; afterwards it was bile-stained fluid, then it was coffee-coloured, and lastly it was clear The vomit was intensely acid, scalding the throat and making it resemble the scarlet fever throat. The pupils were different in size and did not respond to light (Argyll-Robertson sign). The knee-jerks were quite brisk. The patient had not had syphilis. He had had some attacks of pain so severe as to keep him awake at night and he experienced some difficulty in starting the act of micturition. He had had temporary analgesia over the thorax.

Mr. David Wallace showed the Middle Lobe of the Prostate removed by Suprapubic Cystotomy. The specimen was from a man, aged 68 years, who suffered from extreme hæmaturia and required the constant use of the catheter. The bladder was opened in order to rest it, but the prostate was found to have a well-marked pedunculated middle lobe very suitable for removal which was done. The recovery was perfect and within six hours of the operation the urine was free from blood. On the sixteenth day the patient passed urine per urethram and did not now require to use the catheter.

Dr. Byrom Bramwell exhibited a Tumour of the Right Frontal Lobe.—The patient was a man, aged 23 years, who in 1897 showed the general symptoms of an intracranial tumour. Vision was entirely lost in the right eye; the knee-jerks on both sides were exaggerated. There were no localising symptoms and the memory and mental condition were good. He was trephined over the right motor area with relief to the headache, but a degree of hemiplegia ensued. A large hernia cerebri formed and soon grew to the size of a man's fist. He was discharged in July, 1897, and lived until August of this year. The hernia increased in size until it was as large as the head itself (21½ inches in circumference and five and a half inches deep). There was a constant drain of fluid from a small aperture. The great points of interest were the absence of localising symptoms and the large size of the tumour, which destroyed almost the whole of the frontal lobe, and the fewness of the symptoms.

The following gentlemen were elected as office-bearers for the ensuing session:—President: Dr. Alexander Gordon Miller. Vice-Presidents: Dr. James Dunsmure, Dr. Charles Underhill, and Dr. James Andrew. Councillors: Sir John Batty Tuke, Dr. McKenzie Johnston, Dr. Graham Brown, Mr. David Wallace, Dr. John W. Ballantyne, Dr. George Kerr, Dr. Kenneth Douglas, and Mr. H. J. Stiles. Treasurer: Dr. Harvey Littlejohn. Secretaries: Mr. I. M. Cotterill and Dr. Melville Dunlop. Editor of Transactions: Dr. William Craig.

A large number of new members were admitted to the society.

Sheffield Medico-Chirurgical Society.—A meeting of this society was held on Nov. 8th, Dr. E. Wearne Clarke, the President, being in the chair.—Dr. A. J. Hall showed the following cases:—1. Dermatitis Herpetiformis in an elderly woman. The affection had lasted on and off for four years, during which the patient had had repeated attacks of polymorphous painful eruptions in almost all parts of the body. At present there was no eruption but intense pigmentation wherever the spots had been. 2. Eczema of the Hands and Face due to occupation—"occupation dermatitis." The patient, a young woman, was a "wiper of pocket-knife blades," in which avocation she used lime freely. Acute dermatitis attacked both hands and was followed by a similar affection of the face. Dr. Hall contended that there was no hard-and-fast line between eczema and so-called occupation dermatitis and that it was inaccurate to cease to designate as eczema an affection which would otherwise be classed as such directly an external irritant had been discovered. In this case the eruption on the face was not the direct result of the irritant but a reflex secondary outbreak in a distant part of the body. 3. Two cases of Lupus Erythematosus in elderly women. 4. Tertiary syphilide presenting unusual appearances, being probably modified by occurring in a seborrhœic patient.—Dr. W. T. Cocking showed (1) a case of Pseudo-hypertrophic Paralysis in a boy, aged eight years; and (2) a case of Charcot's Disease of the Right Knee in a woman, aged 49 years.—Mr. C. Atkin read notes of a case of Obstruction of the Bowels from Tuberculosis ending Fatally from Hæmorrhage. A woman, aged 37 years, was sent to the Royal Infirmary suffering from obstruction of the bowels. After copious enemata, &c., the bowels were well opened. The symptoms then pointed to hypostatic pneumonia though some abdominal tenderness persisted. The woman was enormously fat and enteric fever was excluded. After a fortnight's irregular temperature hæmatemesis occurred, followed by copious bleeding from the bowel. Post mortem, three or four large tuberculous ulcers were found, the alimentary canal from the duodenum downwards was full of blood, the peritoneum was studded with masses of tubercle beginning to caseate, and with miliary tubercle. No ulcer was found in the stomach, therefore the blood must have regurgitated through the pylorus.—Mr. Atkin also related notes of a case of Gastric Ulcer for which pyloroplasty had been tried. Though symptoms had persisted for five years no ulcer was discovered. The operation was chosen in preference to gastro-enterostomy as the pylorus was free from ulceration, though spasmodically stenosed. The girl gained considerably in weight after the operation. The menses were never irregular.—Mr. Atkin also showed a young married woman, aged 26 years, on whom he had performed Colotomy for Cancer of the Upper Third of the Rectum. There was a history of pelvic cellulitis on the left side six months before, and no other symptoms till those of acute obstruction of the bowels appeared. The growth was fixed and could not be brought up into the wound; there was secondary growth in the peritoneum.—Mr. Atkin also showed a Uterus which he had removed for cancer which was apparently localised to the interior of the organ.—Dr. J. W. Martin read the notes of a case of Acute Inversion of the Uterus in a primipara, aged 26 years. Six hours after a perfectly normal labour the patient became collapsed and profuse hæmorrhage set in. The inversion was reduced by taxis and the patient made a good recovery.

West Kent Medico-Chirurgical Society.—The second meeting of the forty-fourth session of this society was held at the Royal Kent Dispensary, Greenwich, on Nov. 2nd, Dr. Septimus Sunderland, the President, occupying the chair.—Dr. James Donelan read a paper on Tracheal Hæmorrhage as a Sequel of Influenza. He drew attention to this affection as a source of error in the diagnosis of the cause of hæmoptysis. The evidences of the disease were a history of recent influenza, persistent cough with tickling in the throat, the occurrence of hæmoptysis in quantities varying from a few drops to four or five ounces in 24 hours, and an absence of fever except temporarily when the amount of blood lost was large or when the patient was much alarmed. The most important evidences were the laryngoscopic observation of congestion of the veins of the subglottic plexus and the occurrence of bleeding in this situation. These could only be observed with certainty in the period of calm which intervened between one attack and another and while a little oozing from the veins was still going on. The veins in most of the cases appeared to follow the direction of the inter-cartilaginous spaces, though sometimes they formed a close plexus crossing over from one space to another as far down as the fifth or sixth ring. Dr. Donelan had collected 12 cases occurring in hospital and private practice from 1895 to the present time. Nine of the patients had made good recoveries and had never had any trace of pulmonary trouble. Three developed pulmonary tuberculosis and two had died. The reason for the inclusion of these cases amongst the 12 was that there was no evidence of tuberculous infection when the hæmorrhage occurred and chiefly because it was observed to proceed from the subglottic venous plexus and not from any point lower down. The treatment was that commonly employed for pulmonary hæmorrhage—rest, opium, ice, hamamelis, and ergot or ergotin. Dr. Donelan referred to the absence of literature on the subject of tracheal hæmorrhage; the only article on the subject that he was acquainted with was that of Professor Massei, which appeared last year in the Italian Archives of Laryngology, entitled "*Chronic Hæmorrhagic Tracheal Catarrh.*" The cases, however, did not occur in connexion with influenza, though in other respects the history was the same. Professor Massei had also expressed surprise that an affection which must be of somewhat frequent occurrence and which might easily lead to serious error in diagnosis should be practically unnoticed in medical literature.—Dr. F. Moon, Dr. F. T. Taylor, Dr. F. S. Toogood, Dr. J. H. Keay, and Dr. Weekes took part in the discussion which followed.—Dr. Donelan then gave a demonstration of a Few of the Commoner Positions adopted in the Operation for Naso-Pharyngeal Adenoids. He was strongly in favour of the position with the head *extended over the end* of the table, as it permitted a more deliberate and careful removal of the offending tissue and was free from most of the sources of danger and inconvenience which rendered the sitting or lateral positions objectionable.—A discussion followed. A vote of thanks to the lecturer concluded the proceedings.

Manchester Medical Society.—A meeting of this society was held on Nov. 7th, Dr. T. O. Railton, the President, being in the chair.—Dr. Thomas Harris, in opening a discussion on the Open-air Treatment of Tuberculosis, referred to the pathological and clinical evidence which they had of the arrest of pulmonary tuberculosis. He considered, however, that it was much better to speak of an arrest of the process rather than to describe it as a cure, as so frequently the disease became lighted up again. He described the various points in the open-air treatment. The putting on of a large amount of fat which so many of the patients did under the treatment was not to be considered in every case a satisfactory feature, as *this putting on of fat* was sometimes associated with a great amount of discomfort to the patient, and in a large number of cases, although fat was accumulated, the pulmonary disease was not stayed. Dr. Harris referred to the importance of providing sanatoria for advanced cases and thought that such would be especially advantageous to medical officers of health in preventing an extension of the disease. He also considered that investigations as to the cause and prevention of tuberculosis should occupy a foremost place in any crusade against the disease and that more was to be hoped from a study of preventive medicine than from the open-air treatment of tuberculosis in sanatoria or other places. Dr. Harris referred especially to the great danger which existed of sanatoria being conducted by unscrupulous persons, or of their becoming places of quackery, or places where payment of a dividend was the first consideration; and although there were many satisfactory and well-conducted sanatoria in this country he considered that medical men should be very careful as to what sanatorium they recommended to their patients.—The following gentlemen took part in the subsequent discussion: Professor S. Delépine, Dr. James Niven, Dr. H. R. Hutton, and Dr. E. S. Reynolds.

Glasgow Pathological and Clinical Society.—A meeting of this society was held on Nov. 12th, Mr. H. E. Clark, the President, being in the chair.—Dr. James Kerr Love read a paper and demonstrated cases showing the Evolution of the Mastoid Operation.—Dr. Henry Rutherfurd showed: 1. The Parts from a Post-mortem Examination on a case in which Cholecystenterostomy had been performed six months previously for Intense Jaundice. There were a tumour of the head of the pancreas, gall-stones in the common duct, cholangitis, and abscess in the lungs. The bimucous fistula had closed and infection had probably travelled from the bowel up the common duct, the papilla of which had not been absolutely occluded. 2. Specimens illustrating Thrombosis and Embolism in Surgical Conditions. 3. Parts from two cases in which Innominate Aneurysm had been treated by Distal Ligature. 4. A Head, a Tumour, and a Spinal Cord from a case which had been operated on for Encephalocele.—Dr. R. S. Thomson showed samples of Intestinal Sand from Six Cases. The condition occurred in the subjects of mucous colitis and was perhaps not so uncommon as was supposed.—Dr. J. McGregor Robertson showed Ehrlich's Ocular and demonstrated its use in counting blood corpuscles.—Dr. J. S. McKendrick showed a series of Blood-film Preparations.

Folkestone Medical Society.—A meeting of this society was held on Nov. 2nd, Dr. Tyson, the President, being in the chair.—One new member was elected.—Mr. H. A. Powell read notes of a case of Congenital Heart Disease developed at the age of three years, accompanied by a gangrenous condition of the gums, and leading to necrosis of the jaw. Perchloride of mercury was applied and the child eventually recovered.—Mr. Powell also related the case of a vigorous and healthy man, aged 48 years, who was suddenly attacked by Diffuse Cellulitis of both buttocks and perineum due to a perforating ulcer of the rectum high up. On the second day of the acute symptoms free incisions were made and at a depth of four inches a mass of foul sloughing tissue was laid open Antistreptococcic serum was also injected. Mr. T. Bryant and Dr T Eastes both saw the case in consultation. The patient made a good recovery. The sloughs came away on the fifth day, most of the wounds healed in three weeks, and he left his bed in another fortnight. Mr. Powell remarked on the probable origin of the case and its bacteriological aspect.—Dr. Eastes, Dr. P. G. Lewis, Dr. Livington, Dr. W. J. Tyson, Dr. Chubb, and Mr. W. F. Chambers also spoke.

Clinical Society of Manchester.—The opening meeting of this society for the current session was held on Oct. 16th. The following office-bearers for 1900-1901 were elected. President: Mr. F. A Southam. Vice-presidents: Dr. T. A. Helme and Mr. J. E. Platt. Honorary Treasurer. Dr. C. H. Braddon. Honorary Librarian: Dr. J. W. Smith. Committee: Mr. W. G Booth, Mr. G. H. Broadbent, Dr. A. Brown, Dr J. Gray Clegg, Dr. J. Daniel, Dr. W. E. Fothergill, Dr. J. W Hamill, Dr. James Holmes, Mr. C. F. H. Kitchen, Dr. M P. Ledward, Dr. E. T. Milner, Dr. R. T. Parkinson, Dr. E. S. Reynolds, Mr. J. Rust, and Mr. F. H. Westmacott. Honorary Auditors: Dr. A. B. Fulton and Dr. E. J. Walker. Honorary Secretary: Mr. J. H. Ray.—The President opened a discussion on the Treatment of Appendicitis (Medical and Surgical) in its three following forms: (1) Simple or catarrhal (non-suppurative); (2) suppurative (*a*) local abscesses, and (*b*) diffuse suppuration (purulent peritonitis); and (3) recurrent appendicitis.—An interesting discussion followed.

West London Medico-Chirurgical Society.—An ordinary meeting of this society was held on Nov. 2nd, Dr. P. F. Schacht, the President, being in the chair.—The minutes of the last meeting were read and several new members were elected.—Mr. T. R. Atkinson showed a card specimen of Tubal Pregnancy.—Mr. J. Jackson Clarke showed two patients illustrating some points in his paper on Some Phases of Rheumatoid Arthritis and Gout. This paper was, however, postponed by consent until the next meeting in order to give time for the reading of a paper by Mr. G. Lenthal Cheatle on Some Personal Experiences of the late Boer War. The paper was illustrated by a very fine collection of photographs which were shown on a screen by means of a lantern. Mr. Cheatle also showed a number of shells, bullets &c., collected from the battlefield.—A hearty vote of thanks was accorded to Mr. Cheatle for his interesting paper and the meeting terminated.

Reviews and Notices of Books.

Life and Letters of Thomas Henry Huxley. By his Son, LEONARD HUXLEY. London: Macmillan and Co. Two vols. 1900. Pp. 1007. 13 engravings. Price 30*s.* nett

TWO royal octavo volumes, including over one thousand pages between them, make a very large book, but not by any means too large a book to devote to the life of Huxley, crowded as it was with incident and varied by the most diverse public and private occupations. And when we had read the book our wonder was rather how so much had been included in the space. Mr. Leonard Huxley presents us with a complete account of his father's chief writings, doings, and sayings; but he has effected a saving of space by forbearing to attempt a critical digest of Professor Huxley's contributions to biological science. For such a digest other modes of publication are, no doubt, preferable. Incidentally, it need hardly be said, there is a great deal of comment upon biological discovery and philosophical view; but here, as elsewhere, the biographer wisely allows Professor Huxley to tell his own story, and that mainly by means of letters.

The feature of these two volumes is, in fact, the enormous amount of correspondence, dating from the very late "forties" and extending to three days before the death of Professor Huxley in 1895. These letters afford no evidence of priggish compilation for the purposes of subsequent publication; on the contrary, indeed, they sometimes verge upon the indiscreet, as letters written between friends are apt to do. But Mr. Leonard Huxley, by the judicious use of dots, dashes, and initial letters, has pruned away all that could possibly cause any annoyance, however slight, to persons living or to the relatives of those who are now dead. Professor Huxley was, as everybody knows, one of those who fearlessly expressed his opinions and that with decision and precision; it would be therefore impossible to water down any of his straightforward observations of men and things. "A hammer-handed man," observed an eminent divine to the present writer some years ago—a remark which conveyed, and was probably intended to convey, the impression that Professor Huxley was apt to hit the right nail, and that well upon the head.

The first volume begins with the inevitable searchings after family trees, the eagerness of the search being, however, tempered by an apt quotation from the professor himself, who remarked that "My own genealogical inquiries have taken me so far back that I confess the later stages do not interest me." At any rate, Huxley's father was a schoolmaster at that now suburban but then pastoral place called Ealing. The influences of early surroundings upon a man of genius are often the subject of inquiry and some philosophising, but there does not seem to be a great deal to extract from the early circumstances of Huxley's life. His father had "that glorious firmness which one's enemies call obstinacy"; his mother, he tells us, was a lady of extraordinary energy and emotions. Heredity, therefore, may have done and probably did do a fair amount for the *savant*: but Ealing, Coventry, and Rotherhithe do not seem impressive when we think of Agassiz among Swiss glaciers, and Buckland surrounded by the bones of ichthyosauri and plesiosauri at Lyme Regis. It is a curious example of the wise perversity of fate that Huxley was a biologist *malgré lui*; he wished to be an engineer or at least somebody in the mechanical line. Fate in the guise of Sir Joseph Fayrer walked down the steps of Charing Cross Hospital with young Huxley and directed him to apply for an appointment in the medical service of the Navy. It is interesting but futile to speculate as to whether, if the other event had occurred, we should have had among us a colossal scientific expert. Probably not, since on another page the well-known classification of those who are apt to banish the truth concludes with the superlative "expert witness." Professor Huxley's worst enemy could hardly accuse him of withholding the truth; indeed, he was apt to rub it in with salt and pepper.

The voyage of the *Rattlesnake*, to which ship Huxley was now appointed, was the means of his achieving greatness; it is hardly too much to say that the observations and reflections made upon that journey contained the best part of his subsequent work in pure science. On his return to England he found himself celebrated and was in the following year (1851) elected a Fellow of the Royal Society, the youngest Fellow on record, since the number of elections in each year had been reduced to 15. Huxley's opinion of the scientific men of his day is in many ways remarkable. It shows plainly that a certain hackneyed phrase about the tendency of man to err is by no means a platitude, and is a warning to all of us not to be too positive in our judgments as men, and perhaps also as examiners. The two leaders in zoological science are said to be Owen and Edward Forbes. "The rest of the naturalists stand far below these two in learning, originality, and grasp of mind. Goodsir of Edinburgh should, I suppose, come next, but he can't write intelligibly. Darwin might be anything if he had good health." This order would, we suppose, at the present day be almost exactly reversed. There is a good deal about the late Sir Richard Owen in these earlier pages; Huxley found him kind and courteous, and was gratified at being told by the great anatomist, whom he thanked for his assistance in the matter of the F.R.S., that the election was entirely due to his own merits. At a dinner at the Geological Club Huxley met Lyell, Murchison, De la Beche, and Owen. "Owen was," he wrote to his sister, "in my estimation great, from the fact of his smoking his cigar and singing his songs like a brick." Later, as the world knows well, there was much friction between the conservative followers of Cuvier and the young man who introduced into comparative anatomy a new order of things. The friction led to some smart sayings, and some of the sparks thus evolved are truly Huxleyan in their phrasing. "What a capital title it is they give him of the British Cuvier. He stands in exactly the same relation to the French as British brandy to cognac." In fairness to both great men we give a final appreciation by Huxley of this very nickname, contained in a review of Owen's scientific position. It runs thus: "It was not uncommon to hear our countryman called 'the British Cuvier,' and so far, in my opinion, the collocation was justified, high as the praise it implies."

Huxley is known to his generation for the magnificent clearness and sanity of his views and the large range of his outlook. He not only had sympathies that were boundlessly broad, but a gift of expression and exposition both with tongue and pen. "If my opinion were to be taken," says Montaigne, "I should think the slow speaker would be more proper for the pulpit and the other for the bar." As we knew him Huxley was a deliberate and impressive speaker, and it is clear that he in the main occupied the pulpit, though at times he was an advocate rather than a preacher. One of these latter occasions is dealt with by his son at some length. We refer to the celebrated meeting of the British Association at Oxford in 1860, the year after the publication of "The Origin of Species." It was held at that time by men of leading, if not of light, that Darwin's explanation of the cause of evolution was, as Professor Lankester has aptly put it elsewhere, a "capricious and anti-theological assertion that men are descended from monkeys." This was the limited view of persons of real culture and education. At the long west room at the Museum, now occupied by the library, the evolutionists, the anti-evolutionists, and their supporters held forth on Saturday, June 30th, in that year. The Bishop of Oxford "spoke for full half an hour with inimitable spirit, emptiness, and unfairness. ...... In a light scoffing tone, florid and fluent, he assured us there was nothing in the idea of evolution; rock pigeons were what rock pigeons had always been. Then turning to his antagonist with a smiling insolence he begged to know was it through his grandfather or his grandmother that he claimed his descent from a monkey?" A great deal of obloquy has been heaped upon the bishop for his part in the proceedings of that *historic day*; *no doubt he appealed to the ignorant* prejudices of his hearers who were naturally in those virtuous days of horse-hair furniture gratified by such an attitude. But *need we crow so very much*? It strikes us *forcibly* that many worthy persons would arise in their might at the present day, and protest in a precisely similar fashion, if doctrines, which they thought impious because they could not understand them, were promulgated by a man of science and then denounced by a bishop. The personality of the bishop appears to us to be purely rhetorical and not to show any of the "insolence" which has been seen in it, and Professor Huxley's reply was fully as vigorous as the speech which preceded it. What chiefly is hard of understanding in these milder times is why *tantæ animis cælestibus iræ*. Huxley was fighting for freedom of opinion and deprecated authority. It is curious that in these latter days, when the positions of affairs are exactly reversed, the same old human love of authority should crop out in precisely the same way. Freedom of opinion then meant the right to hold more or less the Darwinian views on the origin of species. Nowadays it almost means the right to dissent from them. In presenting a Royal Society medal to Darwin the *President of the Society of that day was carefully* watched by Huxley, who suspected him of the intent to introduce some observation depreciatory of natural selection. The slighting remark was duly made, and that was, perhaps, the last flicker of the fierce flame that raged and attempted to destroy the natural explanations of the phenomena of Nature. Now the flame is precisely as vigorous, but it has been kindled by the then opposition, the school that in the "sixties" was fighting for freedom of thought. Quite recently a book purporting to overthrow some of the conclusions of Darwin and his adherents was published and was reviewed in savage terms because of its attempt to criticise the founder of modern zoological speculations. On the other hand, the most ridiculous assumptions, if they tend to support natural selection, are at once accepted and their authors more than occasionally lauded with surprising fulsomeness. We write as *orthodox believers in the generally* accepted teachings of evolution, but with some doubts upon details. And whatever may be the right way to clear up these doubts, which we share with many people, the wrong course is to stifle discussion. It is noteworthy that Professor Huxley did not commit himself to some of the more extravagant excrescences which have now appeared upon the very trunk of the Darwinian tree of knowledge.

From such a mass of information as that with which Mr. Leonard Huxley presents us in these volumes it is hard to pick out plums of general interest, not in the least from the lack of them but from sheer embarrassment of riches. Huxley knew intimately a large proportion of the illustrious people of his time and as he lived a long life the list is almost interminable. His strong *objection to statesmen was natural in a* man of his constitution and is made abundantly obvious again and again. In inviting Ministers to the dinner of the Royal Society Huxley, "thinking to please the *Society*, made a shot at some Ministers. The only two I know much about are Harcourt and Chamberlain, and the devil (in whom I now firmly believe) put it into my head to write to both. The enormous stupidity of which I had been guilty in asking Chamberlain under the circumstances ...... never entered my head until this afternoon." He did not think highly of our statesmen as philosophers. There are criticisms of Lord Salisbury's address to the British Association at Oxford and of Mr. Balfour's philosophical speculations. Of the latter his estimation sinks lower and lower the more he reads of the "Foundations of Belief." Gladstone, as everyone knows, was severely handled by him in the *Nineteenth Century*. There is an amusing tale told about Carlyle. Huxley confesses to the great influence which the sage had had upon him, *particularly because he* "had *inspired* him with his undying hatred of shams and humbugs of every kind." But it appears that the veneration was not by any means returned. "Years after [the publication of '*Man's Place* in Nature']," writes Mr. Leonard Huxley, "near the end of his life, my father saw him walking slowly and alone down the opposite side of the street, and touched by his solitary appearance crossed over and spoke to him. The old man looked at him and merely remarking, 'You're Huxley, aren't you? The man that says we are all descended from monkeys,' went on his way." The great Napoleon's nephew, the Prince of Canino (why does Mr. L. Huxley give him the sporting title of "Casino"?), noted in his day as an ornithologist, attended the first meeting of the British Association which Huxley attended. He is described as being "singularly like the portraits of his uncle, and seems a very jolly, good-humoured old fellow. I believe, however, he is a bit of a rip. It was remarkable how proud the Quakers were of being noticed by him." The last sentence is somewhat cryptic to us. *Of Darwin there is* naturally much said. A large number of letters exchanged between these two great men are given in full by Mr. *Leonard* Huxley. "The cheeriest letter-writer I know" was Huxley's verdict upon the promulgator of Natural Selection. To be able to address that revered person as "My dear Darwin" seems to us to be the most dizzy height of eminence at which a man could arrive. Copious letters, mainly to Sir J. Hooker, Sir Michael Foster, and Professor Tyndall, deal with every possible variety of topic, from scientific questions of the day and of the past to views upon the conduct of Governor Eyre of Jamaica, the proposed Gresham University for London, and the sea serpent. It was his interest in, and clear expression of views upon, such matters of general talk that really gained for Huxley his widely extended fame. To the general public he was a strong exponent of views generally at variance with *those of respectable mediocrity*; he was not pictured as the hard-working student sitting among bones and fossils and producing monograph after *monograph of fundamental* importance. Towards the end of his life a physical incapacity for bending over a dissecting-table unfortunately cut short the steady output of contributions to science which had marked all of his previous career. But when busy with all kinds of commissions and other duties he would jump into a cab and snatch a brief half-hour of zoological work in his laboratory at South Kensington. We mention this because Huxley the breezy critic of men, manners, and systems has rather dimmed the public recollection of Huxley the great biologist.

One side of Huxley's character is admirably developed by his son in these volumes. Huxley was as delightful and whimsical in his private and family life as he was uncompromising in his public life. The following letter was written to a daughter who had requested an autograph for a friend:—

The Epistle of Thomas to the Woman of the House of Harold.

1. I said it was an autograph book; and so it was.
2. And naughty words came to the root of my tongue.
3. And the recording angel dipped his pen in the ink and squared his elbows to write.
4. But I spied the hand of the lovely and accomplished but vagabond daughter
5. And I smole; and spoke not; nor uttered the naughty words.
6. So the recording angel was sold;
7. And was about to suck his pen.
8. But I said, Nay! give it to me.
9. And I took the pen and wrote on the book of the autographs letters pleasant to the eye and easy to read.
10. Such as my printers know not; nor the postman; nor the correspondent who riseth in his wrath and curseth over my epistle ordinary.

It will be consolatory to all our readers who have ever failed to obtain an appointment which they sought to learn that Huxley was for long most unfortunate in his attempts to secure a professorship. Three places refused him—viz., Cork, Aberdeen, and Toronto. The professors of that day in these universities cannot be congratulated upon their insight; however, after a lapse of 50 years or so it is somewhat of an anachronism to be angry with the stupidity of one's forerunners.

Mr. Leonard Huxley concludes these two fascinating volumes with a list of his father's "Essays, books, and scientific memoirs," which fills no less than 16 pages, and with an excellent index.

The Theory and Practice of Hygiene (Notter and Firth). By J. LANE NOTTER, M.A., M.D. Dub., Professor of Hygiene in the Army Medical School, Netley, Colonel, Royal Army Medical Corps, &c.; and W. H. HORROCKS, M.B., B.Sc. Lond., Assistant Professor of Hygiene in the Army Medical School, Netley, Major, Royal Army Medical Corps. London: J. & A. Churchill. 1900. Pp. 1085. Price 25*s*.

WE are glad to welcome a second edition of this work and to see that although it has been considered desirable to re-write many of the former chapters and to make several alterations it has not been found necessary much to increase the size of the volume. The book is still used as a manual and is, indeed, the standard manual in hygiene both in this country and in America; but if its size be further increased it will pass from the manual class into a different category—a change which many would regret. The present volume contains but 51 more pages than the first edition, yet space has been found for 39 pages devoted to the bacteriological examination of water, a subject which during the last few years has assumed a position of great importance, equalling, if not surpassing, that of the chemical analysis. For this portion of the work Colonel Notter is indebted to Major Horrocks, the assistant professor of hygiene in the Army Medical School. Major Horrocks's special section deals with his subject systematically and, considering the space, very lucidly; he treats of the "collection of water for bacteriological examination," of "quantitative bacteriological analysis" (which he points out is of less importance than the qualitative), of "the preparation of water plates," of "qualitative bacteriological examination," and of the classes of micro-organisms. He then devotes some pages to the experimental researches on the duration of life of the bacillus typhosus in water and sewage and to the methods which have been suggested for the demonstration of the bacillus typhosus in water and to those proposed for the isolation of the cholera spirillum from water. There is a succinct summary of the procedure recommended for the bacteriological examination of water and a page on the methods of testing water filters will be found very useful. Major Horrocks's work shows very considerable thought and care and he is to be congratulated on having contributed much valuable independent information to this new edition. Miss Triscott is also to be highly commended for the pains she has taken in the preparation of the five new plates illustrating this section of the work.

During the last few years many aspects of hygiene have undergone rapid changes and the law of progress has shown itself in almost every part of the science. The parts of the volume now under review which show the most considerable alterations from the subject matter of the first edition are those relating to water-supplies, sewage disposal, immunity, disinfection, and infective diseases.

The chapter on Water occupies 142 pages, 22 more than in the first edition; in it all that is valuable in chemical analysis is accurately set forth, so that the careful student can with its aid carry out the various processes without difficulty. The portion of the work which treats of Air, Ventilation, and Heating is practically the same as in the former issue and is of the highest value.

In the fourth chapter, on Food, there is a useful section under the heading Shell-fish and Infection, in which Dr. Bulstrode and Dr. Klein's report to the Local Government Board upon oyster culture in relation to disease is epitomised and the late Sir Richard Thorne's summary is given in five short paragraphs. The characteristics of the outbreaks of disease transmitted by milk, as set forth by Mr. W. H. Power, are brought prominently forward and the question of the preservation of milk receives considerable attention.

In the section on Habitations much useful and practical information on the important question of Hot-Water-supplies is introduced.

Chapter X., on the Disposal of Sewage and Refuse, has been considerably amplified. Here, under the Purification of Sewage by Biological Methods, the most modern processes are described, such as Dibdin's or the Sutton System, the Septic Tank System, the Thermal Aerobic Sewage Filter of Whittaker and Bryant, the System of Open Septic Tank with Double Filtration in Bacterial Filter Beds, Ducat's Aerated Bacterial Self-acting Filter, and the Purification of Sewage by Intermittent Bacterial Treatment of Coke Beds as studied by Clowes and Houston for the London County Council, and to this portion of the manual there are other important additions.

In the chapter on the Infective Diseases there are some excellent new pages on immunity and protection; here artificial immunity, passive immunity, the origin and mode of action of antitoxins, anti-microbic serum and natural immunity are in turn considered, and a new section is devoted to the etiology and prevention of beri-beri. New paragraphs have also been introduced under the heading of Enteric Fever, describing preventive inoculation, as inaugurated by Professor A. E. Wright and Major D. Semple, R.A.M.C., of Netley, with a description of how the vaccine is at present prepared. It is also stated that the results obtained by Professor Wright's inoculations in India are distinctly encouraging. The Malarial Parasites and the prevention of malarial fevers are dealt with in some interesting pages, while the marked diminution in the fatality of scarlet fever at all age-periods is emphasised, and Dr. Newsholme's table is quoted. This chapter on Infective Diseases occupies 100 pages and is by no means the least interesting and valuable.

Much of the section on Disinfection has been re-written and here there are several new woodcuts to aid the student; the value of formaldehyde as a gaseous disinfectant is dwelt on, but it is pointed out that when Schering's method is employed as a rule too few tablets are used to insure thorough disinfection.

In the chapter on Vital Statistics there are some good tables gathered from Dr. Tatham's figures for the years 1890–92, and observations on the question of occupation in relation to mortality. The paragraphs in which the relation of the density of the population to mortality is discussed are also amplified.

Much of the chapter on Military Hygiene (Chapter XIX.) has also been re-written so as to bring it up to date and to make it inclusive of the most recent regulations. Under the heading of War Rations the daily ration for each officer and man in our recent expeditions is set forth. The chart given at page 1028 shows the difference in the admissions for primary venereal sores amongst British troops before, during, and after the Contagious Diseases Acts were in force at 14 protected and 14 unprotected stations in the United Kingdom.

Appendices XI. and XII. are new—the former deals with the Sterilisation of Apparatus and the Preparation of Culture Media and the latter with the Preparation of Ammonia-free Distilled Water. A new table (after Vieth) is also given for correcting the specific gravity of milk according to temperature.

The new parts of this work appear to us to be excellent and the whole book has been carefully edited. Many mistakes in the first edition have been corrected, and although the present edition cannot be said to be free from errors, most of these are evidently due to the printer and are so palpable that they will not long trouble the student. The letterpress is illustrated by many new explanatory woodcuts which are at once both simple and practical. The bibliography and references throughout the book are excellent, the authors having followed the useful plan of having a separate bibliography at the termination of each subject. We can strongly recommend the volume which will doubtless have as large a circulation as its excellence deserves. The book is a very worthy successor to the well-known work of the late Professor E. A. Parkes, which was subsequently enlarged and edited by the late Professor de Chaumont.

We are glad to see that Colonel Notter mentions Major R. H. Firth's name in the preface, as it appears to us that much of the information in the present volume is as that officer left it when he co-edited the first issue in 1896, and that a tribute is also paid to Major Horrocks for his help and assistance in bringing out the new edition. The omission of the names of Colonel Notter's colleagues from the cover of the work must of course be an oversight on the part of the publishers, but we would suggest that in future editions, which are sure to become necessary, the names of all the authors should be duly set forth.

Medical Electricity. By H. LEWIS JONES, M.A., M.D. Cantab., F.R.C.P. Lond. Third edition. London: H. K. Lewis. 1900. Pp. 532. Crown 8vo. Price 10s. 6d.

To write a practical text-book on medical electricity which would reach a second edition, at a time when quacks had made the subject distasteful to medical men and when it was regarded by the intelligent public with suspicion, was no mean accomplishment. In the first edition the author found it necessary to allot a considerable amount of space to technical detail in order to place the subject on a scientific basis, which, however, somewhat marred the book, as it rendered it difficult reading to those who were not experts in electricity; but the knowledge of the subject becoming more popular by the almost universal establishment of public electric light supplies, in the second edition it was found possible to omit much unnecessary detail and to give more space to treatment. In the present (third) edition the material has so much increased and the progress made has been so considerable that in order to keep the book within the reasonable compass expected in a text-book the author has found it convenient further to curtail the technical portions, to introduce two new chapters, and to add many illustrations, rendering it more complete and up-to-date. The book is so well known that it is only necessary to notice the additional matter introduced. A new chapter on Dynamo Electricity is clearly and succinctly written, and the use which may be made of the street mains are grouped together under the following heads—(1) the illumination of small lamps for special purposes; (2) the heating of a galvano cautery; (3) the driving of small motors; (4) the operating of small and large induction coils; (5) the charging of accumulators; and (6) the treatment of patients; and in an appendix a list is given of the towns having a public supply, together with details as to the current furnished. The chapter on Statical Electricity has been added to and revised. The Holtz and Wimshurst machines are described at sufficient length, the author being evidently much impressed with the work of Dr. Monell of Brooklyn, for he affirms that the effects which large statical machines can produce are almost startling to those who have been familiar only with the phenomena produced by small machines and that the therapeutic results of their use are obtained so promptly and so easily that it is a pleasure to use them.

An additional chapter is given on the Roentgen Rays which is intended as an outline of the methods and principles concerned, and as it is condensed into some 20 odd pages this must be admitted to be the case, but we wish that the author had found it practicable to allot more space to a subject which has become of such universal application. The chapter is illustrated by a coil and a bi-anodal focus tube. We were disappointed in finding no mention of the application of electric light in the treatment of disease. The book is to be thoroughly recommended; the details suffice for the requirements of a medical man who has not the time to study the subject of electricity exhaustively, and as in the former editions the book raises the position of medical electricity to its proper level and helps to remove the reproach that still clings to the profession for having allowed others almost to monopolise the practice. It may be considered as an admirable text-book for students and a handy book of reference for practitioners.

LIBRARY TABLE.

Nordrach at Home. By J. J. S. LUCAS, B.A., M.R.C.S. Eng., L.R.C.P. Lond. Bristol: J. W. Arrowsmith. 1900. Pp. 60. Price 1s.—Mr. Lucas has made an attempt in his "Nordrach at Home" to supply the necessary information for carrying out the "open air treatment" of pulmonary tuberculosis in the house of the patient without removing him to a special sanatorium or to some expensive health resort. The plan which he proposes is simple, practical, and inexpensive. There is nothing original in his suggestions, which are based on the ordinary principles of hygiene, but they are collated in a form which is likely to prove of use. Probably most medical men at the present day are already acquainted with the details of the treatment as far as they are suitable for domestic application. They may, however, be saved trouble if they refer their patients to this little work.

The Feeding of Infants. By W. LANGFORD SYMES, F.R.C.P. Irel. Dublin: Fannin and Co., Limited. 1899. Pp. 40. Price 1s.—This small work is divided into two sections, one dealing with the feeding of infants under one year old, and the other with that of children over that age. Much useful advice is contained in these few pages. The author insists on the use of modified milk when breast-feeding is impossible and condemns the use of patent or proprietary foods; but what he means by the following sentence, which appears on page 10, is most difficult to understand: "Starchy or '*carbohydrate food*' is most injurious to infants under one year of age; they have no means of digesting it." Considering that in the sentence which precedes it he advocates the use of sugar, apparently Mr. Symes does not include sugar among the carbohydrates. Many authorities, including Jacobi, do not subscribe to the universal condemnation of farinaceous foods, even for very young infants. All are, however, agreed that they should only be employed in very small quantities.

Design in Nature's Story. By WALTER KIDD, M.D. Lond., F.Z.S. London: James Nisbet and Co. 1900. Pp. 165. Price 3*s.* 6*d.*—This booklet will act as a reminder that there are arguments against, as well as for, the conception of natural selection as the main factor in organic evolution. And to the medical mind such a reminder is particularly valuable, for as a profession we are inclined to pronounced conservatism, and having once accepted a theory we are not easily shaken in our allegiance. Although the acceptance of the proposition that there is a design in nature does not necessarily exclude the doctrine of evolution it is clear that Dr. Kidd has a very limited faith in the ordinary forces generally admitted to be the chief factors in evolution—natural selection, for instance. Broadly speaking, his arguments in favour of the "unseen and guiding hand" turn on two pivots—(1) that organic nature is so marvellously and wonderfully made that the end must have been foreseen before the foundations were laid; (2) everything is reciprocally adapted in animate and inanimate nature and has been from the first beginning of life. In a retrospective examination of any completed chain of events in which the links are reciprocally dependent it is as legitimate to assume that the chain of events has followed on predestined lines as to assume that the ultimate result might have been different if one of the component links had given way or owing to accident (variation) had been differently constituted. In the marvellous adaptation to the requirements of the human body of such structures as the nasal and thoracic ducts Dr. Kidd finds evidence of design, and he regards the vermiform appendix not as a vestigial relict dangerous to man, but as a "little sentinel" which stands between the small and large intestine and acts as a "death-trap" for the microbe. Dr. Kidd is right in believing that he is raising a "thorny question" in taking this heretical view of the functions of this apparently ill-adapted organ. The author deserves credit for the bold exposition of his views although it is improbable that they will meet with any general acceptance.

Sanitation and Health. By Brigade-General R. C. HART, V.C., C.B., &c. Revised by Brigade-Surgeon-Lieutenant-Colonel T. H. HENDLEY, V.C., C.I.E., M.R.C.S.Eng., L.R.C.P. Lond., &c. Fourth edition. London: William Clowes and Sons. 1897. Pp 56. Price 1*s.* 6*d.*—This small pamphlet is a revised lecture delivered by Brigade-General Hart to the troops stationed in Rohilkland, a district of India. It offers sound advice on general hygienic and sanitary matters, and is written down to the level of understanding presumably possessed by "Tommy Atkins." The lecture is practically such as would be appropriate for a St. John Ambulance class, with the addition of the local and climatic conditions of India which are likely to influence the health of the soldier being taken into consideration. The fact that the pamphlet has reached a fourth edition and is authorised by the War Office for use in army schools is sufficient evidence of the practical nature of the advice therein contained.

Twice Captured: A Record of Adventure during the Boer War. By the Earl of ROSSLYN. Edinburgh and London: William Blackwood and Sons. 1900. Price 10*s.* 6*d.*—The author tells us that he acted as roving correspondent to the *Daily Mail* and the *Sphere* during the Boer War, and in this volume, which is well illustrated, he narrates his personal adventures and experiences in South Africa. Lord Rosslyn saw a good deal and has consequently a good deal to write about, some of which is interesting and well worth reading, but taken as a whole the book is somewhat discursive and contains, in its earlier pages more especially, too many details regarding occurrences which are more or less common to all travellers. In addition to his account of his captivities Lord Rosslyn adversely criticises the system of "censorship" pursued by the military authorities in regard to the treatment of press correspondents, and has much to say of the general conduct of the war. With the best intentions in the world an author, writing in a free and discursive way of what he heard and saw during a campaign, cannot be always sure of his data, and the conditions in which the writer was placed were not, we fancy, those most favourable for forming any full and impartial judgment in regard to current events and topics. We learn that the book has been withdrawn from circulation.

How We Escaped from Pretoria. By Captain AYLMER HALDANE, D.S.O., 2nd Battalion Gordon Highlanders. Edinburgh and London: William Blackwood and Sons. 1900. Price 1*s.*—We had the gratification of reading this spirited and interesting account of "How We Escaped from Pretoria" on its original appearance in *Blackwood's Magazine*. A renewal of our acquaintance with it now that it is published in separate form has tended to revive and to strengthen the very favourable impression which we derived from its first perusal. It is a graphic and well-told story narrated in a very natural, and therefore pleasant and interesting, way and carrying the stamp of truth with it throughout. Its author tells us that he has been enabled to make some additions to his original account owing to the fact that the near approach of a successful termination to the war enabled him to give a full record of the adventures of himself and his companions and of the material aid which they met with from their own countrymen. This he could not do before without the risk of compromising those who had helped him.

JOURNALS.

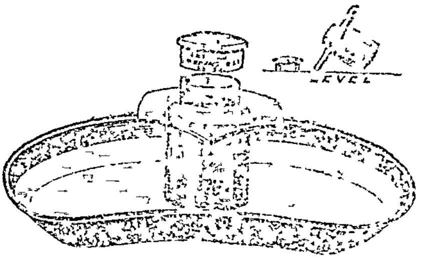
The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY J. HICKSON, F.R.S. Vol. xliv., Part 1. London: J. & A. Churchill. 1900. Price 10*s.*—This part contains: 1. A long and interesting article by Walter Heape, M.A. Cantab., of Trinity College, on the Sexual Season of Mammals and the Relation of the Procœstrum to Menstruation. Mr. Heape points out that in the male the sexual season, called the "rut," from the Latin "rugire," to bellow, and therefore properly limited to such animals as stags and boars and to the male sex only, presents varieties according to whether it is confined to a single period of the year or to certain seasons and should not be applied to those animals which are capable of inseminating the female at all seasons of the year. In the case of the female the activity of her generative organs may be observed when there is no access of the male or when coition does not result in conception and when reproduction does take place. In both cases the changes are complex. He distinguishes between the procœstrum or the period antecedent to heat, the œstrus or period of heat, and the anœstrum or period of rest, intercalating between the last two the metœstrum, which is the period when, conception not having taken place, the excitement of the generative organs gradually subsides. The females of some animals are monœstrous or have only one season of heat—as the bitch or bear—while other are polyœstrous or have many seasons in the course of the year, as the mare Mr. Heape does not consider that ovulation and the œstrus cycle are necessarily coincident. He suggests that there is present in the blood from time to time what may be called an œstrus toxin which stimulates the activity of the sexual organs, and brings about the actual production of those generative elements which nutrition has enabled the animal to elaborate. 2. Mr. Richard Evans, M.A., B Sc, gives a description of Ephydatia Olembingia, a fresh-water sponge. 3 Mr. R. O. Pannett, B.A., describes a collection of Nemerteans from Singapore, with four plates 4. Mr. Arthur Willey describes the Protostigmata of Molgula Manhattensis, a New England species of ascidian. This paper is accompanied by a plate.

The Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, F R S., D J CUNNINGHAM, F R S, G. S. HUNTINGTON, M.D, A MACALISTER, F.R S., and J. G. M'KENDRICK, F.R S. October, 1900. Vol. xxxv., Part 1. With Plates and Figures in the Text. London Charles Griffin and Co., Limited. Price 6s —The contents of the present part are: 1. Atresia of the Aortic Orifice due to Anomalous Development of the Auricular Septum, by Joseph A. Blake, M D 2 Absence of the Inferior Cava below the Diaphragm, by Thomas Dwight, M D, with a plate. 3. The Sternum: its Early Development and Ossification in Man and Mammals, by Professor A M. Paterson of Liverpool, with two plates 4 Some Points in the Anatomy of the Digestive System, by A Birmingham, M D. The author of this paper strongly advocates the use of formalin injections for hardening the tissues and organs of the body and in retaining them in their position. The parts treated of are the salivary glands, the tongue, the palate, the pharynx, the œsophagus, the stomach and intestines, the levator ani, the liver, and the pancreas and the peritoneum 5. The Frequency of an Opening between the Right and Left Auricles at the Seat of the Foramen Ovale, by Professor E. Fawcett and Dr. J. V. Blachford. In 306 cases they found the frequency to be 31·37 per cent 6. Note on the Configuration of the Heart in Man and some other Mammalian Groups, by Dr. Charles J. Patten, with three plates. 7. The True Cæcal Apex of the Vermiform Appendix; its Minute and Comparative Anatomy, by Dr. Richard J. A Berry, with five plates 8 Of the Movement of the Lower End of the Radius in Pronation and Supination and on the Interosseous Membrane, by Dr. James F. Gemmill. 9. The Anatomy of the Ingestive Tract of the Salmon, by Dr G. Lovell Gulland. 10 Archæologica Anatomica: The Parotid, by "A.M." 11. Anatomical Notes and Queries. 12 Proceedings of the Anatomical Society of Great Britain and Ireland.

New Inventions.

AN ASEPTIC DREDGER.

IT has struck me that the whole procedure of an aseptic operation or an aseptic dressing of a wound breaks down when the surgeon who wishes to dust on some antiseptic powder takes hold of a septic bottle or tin for that purpose After the powder has been dusted on the surgeon has, with surgically unclean hands, perhaps to unravel a strip of gauze for packing or to cut a square of gauze to lay over the wound With this idea in view I have devised a dredger made of celluloid which is light, transparent, and can easily be rendered aseptic The dredger is so made as to stand with safety in a basin of antiseptic lotion from which it can be picked out by the surgeon or dresser The bottom of the dredger is weighted so as to keep it in a condition of stable equilibrium if standing in antiseptic lotion of shallow depth, also to keep in position its centre of buoyancy if floated in a deeper basin of lotion. The projecting rim is to prevent water from the surgeon's wet hand, or from the basin, damping the powder inside. The rim also keeps the head of the bottle above water should it get upset, and so again keeps the interior dry Over the perforated disc there is a closely-fitting cap which should always be *in situ* when the dredger is not in use. When the cap is on the whole dredger can be immersed in antiseptic lotion before the surgeon requires to use it I should suggest that the interior of the bottle be sterilised by a tablet of formalin before introducing the powder The instrument has been made for me by Messrs. Reynolds and Branson of Leeds



BERTRAM C. STEVENS, B S Durh., M R C S. Eng.

Leeds.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Nov. 8th, Sir WILLIAM MACCORMAC, Bart, K.C V O., the President, being in the chair.

The SECRETARY reported the death on Oct 27th of Mr. William Anderson, Member of the Court of Examiners. It was then resolved:

> That the Council hereby express their deep regret at the death of Mr William Anderson and their sincere sympathy with his widow and family in their bereavement That the Council do also record their appreciation of Mr Anderson's services to the College while a Member of the Court of Examiners and as Hunterian Professor, and deplore the loss to the College of a Fellow distinguished for his ability as a surgeon and for his refined and cultured attainments

The PRESIDENT stated that the vacancy on the Court of Examiners and the vacancy on the Board of Examiners in Dental Surgery, occasioned by the death of Mr Anderson, would be filled up at the next meeting of the Council in December.

The Council elected Mr W. J. Walsham a member of the Board of Examiners in Dental Surgery (Court of Examiners section).

A report was received from the Finance Committee on the administration of the Sir Gilbert Blane naval medals. The report stated *inter alia* that since the foundation of the fund in 1830 70 medals had been awarded to medical officers of the navy and that a balance of nine guineas remains. New dies for the medal have recently been made at the Royal Mint.

The Council directed that the attention of the General Medical Council should be called to the advertisements of a man at Bury St Edmunds and his illegal assumption of the description "*R D S, R C S Eng*," and they were *requested* to take the matter into consideration with a view to action being taken under Section 13 of the Dentists Act, 1878

The PRESIDENT stated that the Bradshaw Lecture would be delivered by Mr. John Langton on Wednesday, Dec. 12th, at 5 P M., and that the subject of the lecture would be the Association of Inguinal Hernia with the Descent of the Testis.

The Council resolved that the lecture hour for the course of lectures in February and March, 1901, should be 5 P.M.

A SUM of £2350 has been promised towards the Mary Kingsley Memorial Hospital which is being promoted by the Liverpool School of Tropical Medicine. The principal subscribers are local shipowners and merchants whose business connexions with West Africa have made them acquainted with the work of the deceased lady.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 17, 1900.

THE problems of disease are often much more complex than might be supposed, and if this is true of the etiology and pathology of a malady it is equally true of the treatment. In many diseases we are unable to say that our "remedies" have any influence at all on the course of the disease, and this is especially likely to be the case in those affections in which a large proportion of the cases recover even when no treatment is adopted. This is peculiarly true of tetanus. From the earliest times it has been recognised that a certain number of cases would recover and a certain number would die under any form of treatment that might be adopted, and though of late years several new therapeutic methods have been introduced it can hardly be said that we have advanced very far on the road to the successful treatment of this disease. For an accurate estimation of the therapeutic value of any remedy it is essential that the ordinary course of the disease for which it is administered should be well known, otherwise there is great risk of attributing to the treatment the improvement resulting from natural causes.

It is only within recent years that we have had a clear idea as to the etiology of tetanus. Tetanus was until quite lately attributed to those agencies which are invoked when knowledge is deficient. Cold nights after hot days, exposure, privation, were credited with the induction of the disease, yet now we know that though these agencies may predispose to tetanus by a lowering of the vital powers, they can have no real action in causing the disease. It was, however, seen that in nearly all of the cases a definite wound was present, and when the germ theory of many diseases was accepted the thoughts of pathologists naturally inclined towards the idea that tetanus also was due to a microbe. In 1885 NICOLAIER identified the bacillus tetani, and ROSENBACH'S researches in the following year confirmed the theory that it was the cause of tetanus. The next step in advance was the recognition of the fact that the bacillus does not in the vast majority of cases invade the blood stream, but is confined to the vicinity of the spot where it was inoculated. The deductions from this were that only the toxins produced by the bacillus were absorbed, and that these affected the motor centres of the brain and spinal cord. The cleansing or the removal of the local affected area might therefore be expected to lead to a cessation of the manufacture of toxin, and therefore to recovery. But there are two facts which diminish greatly the benefit which might be expected to result from the local treatment; in the first place there is a great risk of re-inoculation of the tissues which have been laid bare in excision or amputation, and in the second place the local removal of the focus of bacilli cannot affect the toxin which has already passed into the circulation. Yet in spite of these defects the local treatment remains one of the most valuable and important factors in the treatment of tetanus. Treatment of the symptoms has been employed for many years, but it cannot be said that much is to be expected from it. Yet sedatives are still rightly considered of value. The internal administration of carbolic acid has been credited with many successes and is well deserving of further trial, though we are ignorant of its mode of action. In 1891 the employment of an anti-tetanic serum was first suggested. It was proved that in a test-tube the serum of an immunised animal has a perfect power of neutralising the toxin from a virulent culture of the bacillus. A similar result was obtained when the toxin and the antitoxin were injected, one immediately after the other, into an animal and the value of serum seemed to be definitely proved. But when the serum was employed in the case of patients suffering from tetanus recovery by no means necessarily followed. In many cases no improvement occurred, though some of the patients recovered; and it was found that no definite reduction in the mortality was effected. Then it was discovered that the antitoxin could neutralise only so much of the toxin as was circulating in the blood stream, and that the toxin had the power of entering into a firm combination with the motor cells of the nerve centres, and that this combination was quite unaffected by the antitoxin. In 1898 it was suggested that as the toxin affected the cells of the brain and the spinal cord it was advisable to inject the serum into the brain or into the subdural space, and this method of administration has been adopted in a number of cases. In some cases recovery has followed. In others death has occurred. The fatal result does not seem to have been in any wise due to the antitoxin, as a rule but in one case the patient recovered from the tetanus and died eight weeks later from cerebral abscess, undoubtedly the effect of the injection. From our present knowledge we may say that the subdural method of administration seems to offer the fittest opportunity for the remedial action of the antitoxin to be manifested.

It seems in the present state of our knowledge that the best hope of the successful treatment of tetanus depends on an early and thorough cleansing of the wound with, if necessary, excision or even amputation, and on the early administration of the antitoxin before the motor cells are irremediably implicated. The very fact that spasms have occurred shows that the toxin has already affected the nervous centres, and the loss of a few hours may suffice to render the antitoxin useless. It may be that in the future a more powerful antitoxin may be prepared which will be able to destroy the toxin even in the central nervous system, but for the present a prompt recognition of the disease and early treatment are conditions essential to success.

* * *

ALL fatalities under anæsthesia are terrible, but there is no doubt that those which take place on occasions when the operation is in itself trifling and not *per se* dangerous to life are peculiarly sad. In this category fall deaths which occur during dental operations. It would not be fair to say that these deaths are preventable, but it may very well be urged that in many instances risks are inflicted upon patients which are out of proportion to the gravity of the operation. In the early days of anæsthesia chloroform was commonly given in dental cases, and SNOW, whose experience was extensive for his day, regarded the practice as safe and justifiable. He even omitted the precautions concerning special preparation, and allowed his patients the sitting posture during the administration and tooth extraction. SNOW never met with a death under chloroform among his dental cases. It would, however, be very misleading were we to argue from this that chloroform is a fitting anæsthetic for such patients and that we are justified in allowing the upright position for persons who are about to inhale the most potent of narcotic vapours. What SNOW could do with impunity the great majority of chloroformists may not do. In the days of SNOW chloroform was not in the hands of every medical man and its use was not of every-day occurrence; to-day there is a danger lest familiarity should breed contempt of dangers. It seems, therefore, well within our province to urge upon the profession the wisdom of adopting anæsthetics less dangerous to life in all cases in which they are available and effectual.

The preference for an anæsthetic which induces a very profound and persisting narcosis in operations upon oral, pharyngeal, laryngeal, and nasal structures is readily explicable. Undoubtedly, chloroform is the most easy of all anæsthetics to manipulate in such cases, and in the facility with which a death-like sleep can be obtained by its use lies its greatest peril. As SNOW employed this agent it was comparatively safe, for after his wonderfully exact experiments he was able to use it for light and transient anæsthesia, always stopping short of the depth of narcosis which is now so often striven for and obtained. In that way lay safety in this danger. Again, while practically everyone can "push" chloroform and obtain a profound anæsthesia few are able successfully to limit its action, and perhaps fewer still to obtain satisfactory results while employing *the anæsthetics of less* potency. It was the failure to obtain uniformly satisfactory results with nitrous oxide gas which led practitioners, especially in Germany, to employ pental and bromethyl. These members of the alcohol series of narcotics obtained a vogue because they possessed the paralysing powers of chloroform without, it was assumed, the lethal perils of that body. However, as WOOD and many others have demonstrated, they are and must be, when their chemical composition and physiological action are considered, as potent as chloroform is potent and safe only in so far as that potency is kept within the range of light anæsthesia. When the fourth degree of narcosis is reached the medullary centres must gradually pass under the influence of the drug employed, and its safety depends then upon whether or not its power to destroy nerve protoplasm is great or small. That of chloroform is great, as is that of bromethyl and of pental, while that of ether is slight, probably as slight as alcohol. That of nitrous oxide, however, is least of all. The use, then, of chloroform or its congeners for anæsthesia in dental operations, if permissible at all, should be restricted to the most narrow limits.

In regard to a case recently reported the following facts are sent to us by the courtesy of Dr. JAMES SAVEGE. The patient, a boy, aged nine years, went to a dentist in Hull to have 10 or 12 teeth removed. The dentist attempted to give nitrous oxide gas, but the boy was "unmanageable" and anæsthesia was not obtained. It was decided then to obtain a medical man's services and after an interval of half an hour chloroform was administered from a wire mask over which lint was stretched. The boy was placed in the semi-recumbent posture in a dental chair tilted back. He struggled slightly. The operation lasted from 15 to 20 minutes, chloroform being given four times at intervals during this time. Six and a half drachms in all were used, being dropped over the lint. The operation was performed after each chloroformisation when the ocular reflex had disappeared. Within a minute of the completion of the operation the boy's face grew ashy in colour and the pulse and heart's impulse were lost. Respiration, which had been steady and regular, failed after growing arrhythmic. The pupils were widely dilated. All measures to resuscitate the boy failed. No note is given as to whether inversion was tried. This clearly was the "first aid" indicated. The reason for using chloroform in this case was that the nitrous oxide had failed, and if we are justified in the assumption that the dentist attempted to administer it and to operate, being single-handed, it is not surprising that his efforts failed. It used to be a common but mistaken idea that nitrous oxide was the special anæsthetic of the dentist and that he could administer it single-handed and operate without detriment to his patient. Possibly a few men of exceptional quickness succeeded, but when it is remembered that the duration of anæsthesia is considerably less than one minute it is obvious that no man can hope to adopt the double rôle of anæsthetist and operator and to do justice to his own powers in either capacity. The reported failure—an actual failure of nitrous oxide never occurs—was no valid reason for the use of chloroform. It may be urged that extensive operations on teeth cannot be performed under nitrous oxide. This is not true. Repeated administrations of that gas, inadvisable as they are when the patient can attend repeatedly, can, in suitable cases, enable a mouth to be cleared at one sitting, especially if ether is employed as an adjuvant. We say in suitable cases, because we hold very strongly that, as the leading members of the dental profession now teach, wholesale extractions are to be avoided, especially when undertaken at one sitting. It must occur in the case of persons of small means that repeated fees are beyond their powers and it then becomes necessary to do the operation at one time. In these cases nitrous oxide can be given intermittently or continuously through a mouth-tube or nasal injector, or the simpler and cheaper method can be adopted of using gas first and producing full surgical anæsthesia with ether. This last method enables a surgeon to remove a jaw *en bloc*, so that if properly conducted it is at least competent for all dental exigencies.

LORD ROBERTS's splendid military services will be ever gratefully remembered by his country, and not least in connexion with the war in South Africa. He has also indirectly done another huge service to civilisation at home. It seems certain that his letter on "treating," published in our issue of Nov. 10th, is having a much wider application than the one which he intended. Lord ROBERTS is naturally jealous for the honour and character of the men whom he has led, of whom he is proud, who "bore themselves like heroes on the battlefield and like gentlemen on all other occasions," whom he "trusted implicitly" and did "not trust in vain." It was his right to speak a few plain words on anything that concerned their welfare to the people of this country whose emotions have been so deeply stirred by the events of the year and whose information on many points connected with the campaign has been as inexact as profuse. And he has cautioned the public as to a particular method of showing their gratitude to the brave troops returning from the seat of war—a method which is full of discredit and dishonour both to the men themselves and to their friends. Right well has Lord ROBERTS spoken. He does ample justice to the honourable bearing and gallantry of our sailors and soldiers and to the keen appreciation of these qualities in the civil population at home, while he implores the people not to show their appreciation by the degrading habit of offering drink. Lord ROBERTS'S recognition of the good sense of the people at home will make them more ready to respect his wishes. Those wishes should command universal attention and no self-respecting man or woman should venture to offer drink to the returning troops in the street or in the public-house Lord WOLSELEY, who, like Lord ROBERTS, has published his views on this matter, has long been telling us that the army is a great school of discipline. And we very much mistake if the many independent witnesses to the character and conduct of our army in South Africa will not confirm the testimony of the two distinguished commanders to the effect that the discipline has reacted splendidly. We know of good judges in the Volunteer force, who have shared the brunt of the war in South Africa with Her Majesty's regular soldiers, and who are resolved that henceforth no one shall speak slightingly in their presence of the virtues of the rank and file of the British army. Why, then, try to tempt them?

It has to be remembered that under short-service regulations a soldier is not only a soldier. Our wars are not his only occupation. He comes from and returns to civil duties after the expiration of his term of service. Such is the proper respect of employers for him that in most cases his civil place is kept open for him if his military duties take him away from civil employment. It is certain that more favour yet will be shown to men who crowd into their life service to the State and service to their employers—always provided that their moral character is not impaired. Here comes the responsibility of the leaders of the army. They wish to restore the men of whom they are so proud as soldiers to their homes and to their employers unimpaired and unbesmirched. He who would intercept the soldier fresh from the field where all his virtues have been splendidly displayed on his way back to civil life and duty, and lure him into an act of vice or drunkenness, may call himself the soldier's friend, but he is the soldier's enemy and should be recognised as such. We believe that the words of Lord ROBERTS and Lord WOLSELEY will conduce to good results. The whole subject of "treating" is one that merits deep consideration. The medical profession has long been teaching that casual drinking is bad. Most "treating" is of this nature. The drink so taken is taken without food; it is taken without needing to be taken; it is superfluous; it leads in a large number of instances to intemperance. From the pulpit no less than from the medical consulting-room these points have been urged without much effect. But now that the ruling spirits of our army have spoken in their support we look forward to reform. The word of our great soldiers will prove, particularly at this juncture, to be more powerful in the reform of our absurd drinking customs than the sermons of preachers or the opinions of men of science, and will counter-balance the harm done by the extreme dogmas of fanatics. What is true for the army is true for the whole population. And especially true for those who live by labour, who need to spend wisely what they make, and who can only rise in the social scale by strength of character and self-denial. Labouring families must suffer some degree of starvation if a third or a fourth of the wages which they earn goes into the coffers of the publican instead of into the coffers of the butcher, the dairyman, and the tailor. The practice of "treating" is wholly bad, because it leads to casual drinking, a habit which lays the foundations of disease. It lessens the sound nourishment of families. It promotes laziness. It degrades the sentiment of self-respect and takes the fine edge off many moral qualities. It powerfully antagonises the remedies of the physician and of the moralist alike.

For which reasons we welcome the formation of any association having as its aim, or one of its aims, the prevention of casual drinking. The Church of England Temperance Society has led the way in this direction. And now we learn that in Scotland a new society has been formed, with His Grace the Duke of SUTHERLAND as President, to be called the "Scottish Self-control Society," or briefly the "S.S.S." The members undertake three things:

1. Not to drink intoxicants before noon or at any time except at a regular meal.

2. Not to treat—i.e., not to offer or to accept alcoholic drinks except with a regular meal.

3. Not to give or to accept drink in return for services rendered.

That in a country like Scotland, famous for its religious, intellectual, and academic superiority, the people, without distinction of church or class, should consume alcohol, chiefly in the strong form of whisky, at all times and on all occasions has long been an inexplicable fact. We do not know whether the "Ten-tumbler Club" still survives, but it is not many years since it existed and included men of high character and celebrity. When elders and professors have been involved in the habit of drinking a poisonous quantity of alcohol daily how could a high standard of national sobriety be expected? The use of whisky by the Scotch has proved infectious, and it has extended to England on a scale which deserves, and is now receiving, the grave study of the medical profession whose authority is too often quoted in its support. We may hope that the time of the strange belief that it is a compliment—a friendly act—to a man to press him to drink is about to pass away. The fact that an important section of Scottish society recognises the baneful influence of casual drinking is of good omen. We are pleased to see in high office in the "S.S.S." a high theological authority like Professor CHARTERIS, D.D., and Sir WILLIAM MUIR, K.C.S.I., Principal of the University of Edinburgh. No class, by adhering to the Society, can do more good both to itself (we regret to say) and to the Society (we are proud to remember) than the medical schools of Scotland. For the medical students of Scotland have generous and hospitable traditions which lead them too often to compliance with the customs which it is the object of the Scottish Self-control Society to destroy. We wish the movement all success.

Annotations.

"Ne quid nimis."

A CORONER'S VIEWS OF MEDICAL EVIDENCE.

ACCORDING to a paragraph in the *Yorkshire Post* Mr. J. S. Walton, M.D. Erlang., L.S.A., one of the coroners of that county, holds opinions with regard to the scope and conduct of inquests to which we must beg to demur. He is stated to have said "that it was ridiculous to think that medical evidence was necessary at all inquests. To have a post-mortem examination on every occasion was a waste of public money to which he was strongly opposed. Some of the members of the county council evidently thought the coroner's court was a court of medical inquiry. It was nothing of the kind, and he thought that the members of a body like the county council ought to know what they were talking about." But were the members of the county council so ignorant that they did not know what they were talking about? and is a coroner's court not a court of medical inquiry or anything of the kind? We will pay the coroner and the county council alike the compliment of assuming that neither ever contemplated the holding of a post-mortem examination in every conceivable case where an inquest is necessary. For example, where a man has thrown himself in front of an express train and has been cut into fragments by the wheels a post-mortem examination in the ordinary acceptation of the term may not be indispensable. The cause of death is hardly obscure in such a case; but is medical evidence therefore not to be heard at the inquiry if it be obtainable? Evidence as to the state of the mind of the deceased would surely be desirable if it could be called. And in any case that does not involve an obvious cause of death, will it not be a source of danger to the community if the true cause is not established by the best possible evidence? It is the duty of the coroner to hold an inquest in all cases of a sudden death where the cause is unknown. Are the plausible suggestions, for example, of relatives to be taken as evidence of how the deceased met his end? Or is it to be borne in mind that inquests are held in order that there may be certainty and that that certainty can only be attained in one way—namely, by considering the evidence of skilled and independent witnesses, for the giving of whose testimony it may be necessary that a necropsy should take place? Of course, in many places where death is reported to the coroner he may not consider an inquest necessary. He may satisfy himself, if he chooses to take the responsibility, even without the opinion of a medical man, as to why the person in question died, and give his order for the burial of the body accordingly. We are not here discussing the wisdom of his taking this course except in very clear cases, but we can hardly see how if he has once decided that the case is one for inquiry he can at the same time expect the jurors to decide rightly without having medical testimony before them. We have pointed out that there may be reasonable exceptions to this, but we assume that these were intended by the county council, of which Dr. Walton appears to have spoken in terms which are the more to be regretted as Dr. Walton himself holds medical qualifications.

EXPECTED VISIT OF COLONIAL TROOPS AND THEIR MEDICAL CORPS.

THERE is a prospect that within a short time London will be honoured with the presence of representatives of the Colonial troops who have done such splendid service in the war in South Africa, including representatives of the Colonial Medical Corps. We trust that the opportunity of showing hospitality to them will not be lost. The medical profession will doubtless devise some way of doing honour to their Colonial brethren, whose services have been so valuable, and we sincerely trust that the way selected will be one in which all ranks and sections of the profession may unite. Probably, after the hardships of war and the discomforts of the sea, our Colonial brethren would much appreciate the private hospitality of their metropolitan brethren and a short experience of the quiet home-life of London.

THE EASTBOURNE GUARDIANS AND VACCINATION.

THE position of a defendant to a plaint in the county court against whom judgment is given for a paltry sum of £2 11*s.* 6*d.* is not at any time one of dignity, still less is it so when a judge of well-nigh 30 years' experience accompanies his decision with the stinging criticism that he has never known a more contemptible or dishonest defence than that which he had just heard raised. It was in this ignominious position that the guardians of the poor at Eastbourne deliberately placed themselves and the district of which they are the representatives by refusing to pay the justice's clerk's fees incurred by their vaccination officer in taking out summonses against various persons for not having had their children vaccinated according to law. The justice's clerk sued the vaccination officer who clearly was primarily responsible, the question remaining whether the guardians were liable to recoup their vaccination officer, and in order that this might be ascertained, by the learned judge's direction the guardians had been added as third parties. The guardians endeavoured to set up the statutory defence that the debt claimed against them should have been paid, if at all, during the half-year in which it became due, or three months after, but they were not permitted to rely upon this as, possibly to show their contempt for the technicalities of the law, they had omitted to give the prescribed notice of their intention to do so. In any case, however, it would not have availed them, as His Honour found that the time ran from the date when they first resolved not to pay, which was some time after the debt was incurred. Their contention that a vaccination officer has no authority to take proceedings without general or specific instructions from the guardians equally failed to convince Judge Martineau; that it should have been seriously raised considering the decisions that have been given upon the subject by the High Court seems strange; and it is not surprising that in the end judgment went against the guardians, accompanied by the remarks quoted above and by a refusal of leave to appeal. The question as to who pays the costs incurred by the unsuccessful defendants in such legal proceedings as these remains. Do guardians in such cases defray them out of their own pockets? They can hardly be justified in taking them out of the pockets of other people unless before they decide upon resistance in a court of law they are advised by counsel of recognised position that resistance is their duty and that it is likely to meet with success.

THE PREVENTION OF TUBERCULOSIS.

A REPORT presented to the vestry of Clerkenwell by Dr. George Newman, medical officer of health of that parish, will be found to contain a useful summary of what is at present known on the subject of the prevention of tuberculous disease. In the latter portion of the report, which has been published in pamphlet form, Dr. Newman gives full details of the precautions which ought to be attended to by the patients and their friends; he also recommends voluntary notification of cases of phthisis, and describes the methods of disinfection which may be undertaken by the sanitary authorities after the death of a patient.

THE INFLUENCE OF CLIMATE UPON MENSTRUATION.

IN THE LANCET of Nov. 10th (p. 1347) Mr. W. J. H. Hepworth recorded a most interesting case of amenorrhœa, in which the patient had found that a visit to the country was sufficient to bring on her periods. With such certainty did this occur that she formed the habit of going out of town for a couple of days in each month when she at once became unwell, although if she remained in London the period invariably failed to appear. Such a marked instance as this of the influence of climate upon menstruation is seldom met with. It is a common enough matter for young women to suffer from amenorrhœa when they first come to London from the country, but so immediate and certain an effect as is apparent in the case recorded is of very rare occurrence. A considerable amount of study has been devoted to the influence of climate upon menstruation. There can be little doubt but that it plays an important part in determining the age at which puberty occurs, but is only one—perhaps, however, the most important—of many factors influencing the result. Marc d'Espine, who made some special investigations upon the subject, came to the conclusion that the onset of puberty varies directly with the latitudes, the tendency being for the first menstruation to occur at an earlier age the nearer the equator is approached. The climate of a country plays, however, a more important part than its latitude, and the variations observed in the age of puberty in different countries bear a close relationship to the average temperature of the air in those countries. Krieger has drawn up an elaborate table showing the exact age at which puberty occurs in different latitudes, and from this it can be seen that while the average age in Swedish Lapland is 18 years, in London it is 14 years and nine months, and in Sierra Leone 10 years. The matter has been almost entirely considered from the point of view of the time of the occurrence of the first menstruation, but the influence of a climate in producing an early or late puberty may well be regarded as indicating its probable effect upon the occurrence or non-occurrence of menstruation after puberty has been established. That climate plays any part at all in the matter has, however, been denied by many authors, who hold that the question is rather one of race and nationality. In support of this they bring forward the fact that women of different nationalities inhabiting the same country under similar climatic conditions do not begin to menstruate at the same age. In Hungary, for instance, Joachim has shown that the average age at which puberty occurs amongst the Magyars is from 15 to 16 years, amongst the Jews from 14 to 15 years, and amongst the Slavs from 16 to 17 years. This fact does not, however, show that the influence of climate is of no importance. To affirm this it would be necessary to prove that women of different nationalities inhabiting the same country under similar climatic conditions for very long periods of years had continued throughout to menstruate for the first time at the same average age. In discussing the onset of puberty many other conditions remain to be considered, such as race, nationality, mode of life, station in life, the early excitation of the sexual feelings, and the question of nutrition and clothing. Mr. Hepworth's case, however, proves that change of climate alone may have a marked effect upon menstruation. Nor is this surprising when we consider that the whole question is largely one of nutrition. Heat and sunlight are amongst the most important factors of nutrition, and the early onset of menstruation amongst the inhabitants of the countries near the equator is no doubt in part due to the great heat and the large amount of sunlight to which they are exposed.

THE QUALIFIED QUACK.

WE record in another page the fact that the Royal College of Physicians of Edinburgh has purged its Register of a name that has for some time brought it discredit with impunity. One of the scandalous advertisements of "Dr. Harman Tarrant" lies before us culled from the trade columns of the *Australasian*, a newspaper which the advertisement requests those responding to mention. The advertiser gives an address at Sydney, and invites those who consult him, if they prefer to do so, to address him at a box rented in the Sydney Post Office. He also informs those who may desire his advice personally or by letter that during his recent world-wide travels he has "discovered a new method of healing,' which, apparently combined with "knowledge of special complaints gained by careful study and observation in the principal hospitals of the world," enables him to cure persons suffering from such "dangerous symptoms" as, for example, indigestion, weak eyes, or a sallow skin; while another paragraph equally skilfully worded in order to bring into his net those who may really need medical or surgical assistance, promises treatment, in return for a fee of £1, for a miscellaneous list of complaints that comprises fistula, piles, constipation, hip disease, Bright's disease, dropsy, and worms. The whole is, in fact, an elaborate and aggravated example of the ordinary quack's advertisement, including the usual promise of a free consultation, but the feature which renders it especially dangerous, a feature to which we have made previous reference, is that the advertiser appends to his name (and until the present action taken by the Royal College of Physicians of Edinburgh had the right to do so) the letters F.R.C.S.E., L.R.C.P.E., L.M.R.C.P.E., L.R.C.S.I. It is obviously unfair both to the general public and to members of the medical profession at work in a distant colony that conduct of this kind should be permitted by universities and corporations in the mother country. Every step should be taken by the authorities as promptly as may be to enable those in the colony to protect themselves. The Royal College of Physicians of Edinburgh has deprived Tarrant of two of his advertised qualifications; it now remains for the Royal College of Surgeons of Edinburgh and the Royal College of Surgeons in Ireland to deal with the other two.

STREET NUISANCES.

IT will be remembered that some time ago the London County Council and representatives of the Corporation of London, the vestries, and the district boards held a conference to consider regulations about the streets and street traffic. A committee was appointed and on Nov. 7th the report of this committee was presented to, and received by, the conference. Several excellent regulations were proposed for the removal of refuse, the chief among them being "that in the opinion of the conference it is highly desirable that in all streets notified by the police as being those where house refuse must be placed on the footway the hour for the removal of the refuse shall be 9 o'clock and not 10 o'clock as at present' Another recommendation was that with regard to the clearing away of snow the old rule which entailed that duty on the householder should be reverted to This recommendation was rejected Nothing further was recommended as regards street cries, and as regards street music the committee reported that they considered it undesirable that street musicians should be required to take out a police licence. They recommended, however, "that wherever two thirds of the householders in any road, street, terrace, or collection of houses sign a notice to the Chief Commissioner of Police that they desire to be unmolested by itinerant musicians the police should be instructed to order such street musicians to move from such locality" The recommendation was adopted Other recommendations dealt with the placing of the names of streets so that they can be seen—a sorely needed reform—and the attention of the police was "invited to the delivery of barrels' We consider that the attention of the police might be profitably called to the delivery of a great many other things besides barrels—biscuits, soap, hampers, flour, and the like, to say nothing of barrows laden with ladders, spikes, and coils of wire with which the National Telephone Company block the footway The Mayor of Westminster might also draw the attention of his brother of Holborn to the filth and mess caused by Covent Garden Market But until that market becomes as great a nuisance as Smithfield we suppose it will linger on The Augean stable of London needs a very Hercules to cleanse it, but we are glad to see that at least the existence of nuisances is recognised We are sorry to see no reference made to the perfectly avoidable mess made by waste paper such as news posters and omnibus and tramway tickets

ON THE CEREBRAL CONDITIONS ASSOCIATED WITH SACCHARINE DIABETES

DR LOUIS DESBONNETS (*Thèse de Paris*, 1900) gives a long account of the above subject, based on the study of 29 cases whose clinical history and symptoms are recorded at some length But little attention has been paid in text books to the cerebral troubles associated with diabetes, Bouchard having stated in 1885 that "the nervous symptoms of diabetes though frequent are but little known" Among the more frequent symptoms recorded by Dr Desbonnets are general muscular feebleness and proneness to fatigue, temporary and transient (sometimes permanent) attacks of hemiplegia and monoplegia which are of an atypical character, neuralgias (Buzzard) affecting by preference certain nerves, such as the sciatic, crural, trigeminal, inter costal, and occipito cervical, and probably indicating commencing peripheral neuritis Visual disturbances, diplopia from weakness and incoordination of the ocular muscles, and temporary attacks of amblyopia are not uncommon. The general cerebral state is one of apathy and loss of all individuality and initiative in conduct Later, ideas of ruin, hypochondriacal melancholia, and delusions of persecution may appear, the particular form of mental disturbance taking its special colouring from any neurotic tendency which may be present (Westphal) Vertigo, headache, insomnia (Pierre Marie), and nightmare are frequent in diabetics The tendency to apathy and torpor may at times deepen into narcolepsy and this may occur periodically The following is one of the surgical cases recorded in the *Thèse* A young shoemaker, of stout build (a tendency which he inherited), had since 1896 suffered from polyuria, especially during the night One morning on waking he was surprised to find that his left leg was paralysed and insensible and could not be moved The following day the arm became similarly affected, and finally the left side of the body grew hemiplegic and hemianæsthetic He was unable to close the left eye and could not see objects in the left half of the visual field (hemianopsia) The eyelid recovered soon after but the general hemiplegia persisted The urine was found to contain 3 3 per cent of sugar and to have a specific gravity of 1035 Polydipsia and dryness of the mouth were present in a marked degree Power returned partially to the left arm and leg The knee jerks were absent Ophthalmoscopic examination showed a normal fundus in each eye Both smell and taste were diminished on the left side and hearing was impaired in the left ear The diagnosis was doubtful, but the symptoms pointed to a partial damage of nerve fibres in the posterior part of the internal capsule of the right cerebral hemisphere Fursterer has found minute capillary embolisms (supposed to be produced by granules of glycogen) in the brains of patients dying from diabetes with symptoms of temporary paresis or paralysis, the more grave cases of persistent hemiplegia showing distinct cerebral foci of softening, and Dr Desbonnets inclines to the same belief

TUBERCULOSIS IN THE FRENCH ARMY

IN a short article published in the *Archives de Médecine et de Pharmacie Militaires* for October Inspector General Kelsch recapitulates his views regarding the incidence of tuberculous diseases in the French army. The admirable labours of Villemin, of Koch, and of their followers have, he says, reduced the etiology of tuberculosis to an expression as simple as it is luminous Monopolised by experimentation, which has constituted its pathogeny upon the image of the disease as observed in animals, forsaken in a great measure by clinical observation, which has been compelled to efface itself before the brilliant notions of the laboratory, tuberculosis in man has become a disease of inhalation and ingestion This being so, the director of Val-de Grâce is convinced that the situation is fraught with danger To begin with, in spite of the incessant anti-microbic warfare during the last 10 years, tuberculosis is still progressing All the artifices of statistics cannot conceal this painful fact The disease causes more damage than ever among young soldiers of less than a year's service, whereas amongst veterans it is stationary or even decreasing Why should there be this discrepancy? Are not all ages equally liable to microbic attack? Moreover, young soldiers suffer chiefly during their first six months which are also the most inclement of the year If tuberculosis were communicable solely by contact from man to man all ages should suffer alike, and no season should be exempt more than another Inspector General Kelsch is firmly of opinion that it is the conscript who infects himself Many conscripts when they reach barracks are the hosts of latent tuberculosis, fibro caseous nodules, solitary or multiple, scattered amongst the mediastinal or the mesenteric ganglia, in the lungs or in some other organ—a condition of things that is perfectly compatible with a vigorous constitution and flourishing health, and one that is not to be detected by ordinary examination In fully a third of the necropsies which he has conducted on subjects who died from other causes than tuberculosis Inspector General Kelsch has met with these hidden lesions and they were likewise present in 51 out of 120 unselected conscripts whom he inspected on joining, by means of the radioscope He believes that the deposits may take place in utero and that most certainly they are of very frequent occurrence during childhood Although latent they are by no means defunct, but, on the contrary, retain the elements of vitality, spores ready at any moment to evolve, veritable sparks which brood beneath the ashes[1] and constitute a perpetual menace for the individual. Inspector-General Kelsch failed in his attempts to implant tuberculosis in 80 guinea-pigs which in the course of one and a half years he inoculated from the sweepings of barrack-rooms at Lyons, but he is nevertheless far from disregarding the dangerous nature of floor dust and fully appreciates the importance of the sputum as a vehicle of contagion. We should not, however, refuse to acknowledge the possibility of auto-infection or fail to adopt measures for the alleviation of so great an evil. The virus of rabies or of anthrax once implanted is strong enough to triumph over all resistance of its own accord, being equal to the task of conquering human vitality unaided; but in the case of phthisis pulmonalis the bacillary enemy is feeble enough to require an ally in the citadel itself, it cannot subdue the garrison unless there is complicity amongst the defenders. Before the bacillus of Koch can effect a serious lodgment in the human organism it must have the assistance of a traitor, and unfortunately the disaffected are numerous, chief among the number being insufficiency of proper food, *surmenage*, defective cleanliness of body and habitation, impure air, dark rooms, and, above all, alcoholism. The only solid prophylactic basis whereon to build in the case of tuberculosis consists in the development of the soldier's physical vigour together with the amelioration of his hygienic and social surroundings.

---

[1] E'en in our ashes live their wonted fires —Gray.

THE HOWARD ASSOCIATION AND STREET RUFFIANISM.

THAT excellent society the Howard Association has issued its annual report dated October, 1900. In dealing with the work of the year the report treats of many subjects, such as reparation to the injured as well as punishment for the injurer, the International Prison Congress recently held at Brussels, admonition and punishment, the housing of the poor, and the rural exodus. In addition to these the questions of juvenile roughs and truants, the Juvenile Offenders Bill, and the temperance question are discussed. With regard to the first of these the association speaks in terms of praise of the children's courts existing in Australia, in which school attendance cases and children's offences in general are dealt with. Such courts would, we think, do good work here, provided, of course, that they were quite independent of the School Board. With regard to the Juvenile Offenders Bill, which was dropped owing to the weakness of the Government in giving way to the cries of faddists, the association considers that if the birching clauses were not to apply to children under 10 years of age the Bill would be a good one. Even Mr. J. A. Picton prefers the birch to the gaol. We can only hope that the Bill will be carried through by the present Parliament and that a pistol clause will be embodied in it. With regard to Hooliganism the report says:—

> "Whilst whipping is a useful check to the worst forms of 'Hooliganism,' the prevention of the evil at its *sources* is of far greater importance Idleness, parental neglect, and want of occupation and of healthful physical exercises are amongst these causes, together with frequent magisterial laxity in failing to support the police."

With this we certainly agree. Magisterial laxity is responsible for much of the excess of violence which has of late been evident in the streets. For instance, at Southwark Police court on Oct. 24th two young roughs, aged respectively eighteen years, were brought before Mr. Kennedy on a charge of "using insulting behaviour." Evidence was given that prisoners belonged to a gang who austled foot passengers and menaced shopkeepers. Mr. Kennedy is reported as saying that "such ruffianism must be put down." And what followed? A fine of five shillings or five days' imprisonment. We can almost hear Mr. Kennedy saying, "D'you know, I shall really have to give you a good hard knock." Such trivial punishment will never check crime. By all means let us use every means of prevention, but the full-blown Hooligan, as we have said over and over again, must be severely dealt with.

THE CARDIFF INFIRMARY.

WE have upon several occasions drawn attention to the unsatisfactory financial position of the Cardiff Infirmary and have expressed astonishment that so excellent and well-administered an institution should meet with such inadequate support from the inhabitants of the district as to leave an ever-increasing burden of debt upon the managers. There is perhaps at the present time no more prosperous town in the country than this South Wales port, and as all classes are participating in the good times there should be little or no difficulty in liquidating the debt of £10,000, the amount which the adverse balance of the past few years has now reached. The erection of the new seamen's accident hospital has no doubt adversely affected the revenues of the infirmary, but now that the establishment of the former institution is assured by the munificence of the late Marquis of Bute the claims of the infirmary may deservedly be considered. The newly-elected mayor of Cardiff, Councillor Thomas Andrews, has already evinced a desire to raise during his term of office a sufficient sum to enable the infirmary to be placed upon a firm financial footing, and at the mayoral banquet held on Nov. 9th last he obtained subscriptions for this purpose amounting to several hundred pounds. We congratulate the mayor upon his benevolent resolve and trust that long before next November we may be able to felicitate him upon the success of his enterprise.

CACODYLIC MEDICATION.

WE have previously referred to this mode of administering arsenic, which has been recently introduced by M. Armand Gautier.[1] A lecture on the subject which was delivered at the Medical Graduates' College and Polyclinic by Dr. William Ewart and which is published in the September and October numbers of the journal of that institution well describes the present knowledge on the subject. Cacodyl is a dimethyl arsenide obtained from AsH_3 by substituting methyl for hydrogen. It is a highly poisonous fluid with an unpleasant odour. In oxide of cacodyl these objectionable features are still present. By further oxidation the metal passes from the triad into the pentad stage forming cacodylic acid. In sodium cacodylate it loses virulence and smell. This organic compound contains 46 per cent. of arsenic and has the great advantage over ordinary preparations of relative freedom from irritating and poisonous properties. In it arsenic can be administered in quantities previously unheard of without misgivings or risks. Dilute solutions are well tolerated by the stomach. Cacodylate of sodium is a highly soluble deliquescent solid free from smell and taste. In consequence of its deliquescence pills cannot be prepared in the ordinary way. Cacodylate of sodium may be given by the mouth or rectum or subcutaneously. The two latter methods have been advocated in preference to the former because they are less liable to lead to the formation of reduction compounds. By the mouth half-grain pills may be given three or four times daily or the equivalent in solution either at or between meals. By the rectum an initial dose of half a grain may be given to adults and a third of a grain to children suffering from chorea. From one to four drachms of water may be used as a vehicle. Hypodermically one-third of a grain in 10 minims of water is an initial dose and may be increased to one grain or more. Moderate doses of the drug may be given for long periods, but the patient should be watched. Cacodylate of sodium may be given with an efficacy greater than that of ordinary arsenical preparations. In all cases in which arsenic is indicated—pernicious anæmia, chorea, malaria, and Graves's disease—even in cancer, particularly of the stomach, it has been declared to be valuable. According to reports from abroad, in phthisis it is the best medicinal remedy that has been used. Dr. Ewart finds that the tendency to hectic fever is checked, cough and expectoration are diminished, and the general condition rapidly improves. He has also found it useful as a nerve tonic in many states of depressed health. This new method of administering arsenic appears to have great possibilities and to be a distinct advance in therapeutics. But, like all new methods, its claims should be regarded with reserve The question of the maximum dose has still to be solved. We observe that Dr. Ewart describes the freedom from poisonous properties as relative. Cannot something more definite be said? However free from irritating properties cacodylate of sodium may be it seems to us that the dangers from remote toxic effects—e.g., neuritis and eruptions—would be just as great from its use as in the ordinary method of administration. Such a powerful remedy as arsenic should not be given in any form in large quantities without great care

[1] THE LANCET, Nov. 18th, 1899, p. 1408, and March 10th, 1900, p. 736.

A CURIOUS INSTANCE OF LEAD POISONING.

IT was reported in the newspapers this week that one of the officers of the Metropolitan Fire Brigade was seriously ill from the effects of lead poisoning, the illness having been caused by the officer, when he was on duty during a fire at a tea warehouse, inhaling the fumes from some of the burning tea-boxes which were lined with lead. The theory of the inhalation of lead fumes is probably not correct. Of course, lead melts very easily at a temperature of 327° C. and eventually boils and volatilises at a white heat It would clearly be impossible for a person to inhale these fumes. If the case is correctly described as one of lead-poisoning arising from contact somehow or other with lead cases in a fire it is more probable that the intense heat converted the lead in part into oxide. It is conceivable then that the smoke and fine ashes scattered broadcast by the draught might contain fine particles of oxide of lead Such a draught would prove undoubtedly poisonous, part of the lead being inhaled and part absorbed through the skin. In that case it is difficult to see why the other firemen in attendance were not also affected; they may have been, but it is not so stated. If the report be true the occurrence is certainly a remarkable one, and as far as we know it is the first time that lead poisoning arising in such a way has been recorded.

BOARDS OF GUARDIANS AND VACCINATION.

AT a recent meeting of the Wigan Board of Guardians a circular letter was read from the Derby Union embodying resolutions passed respecting the Vaccination Acts and including one that it was no longer necessary to retain on the Statute Book a law making the vaccination of infants compulsory. It was moved and seconded that the resolutions should be endorsed and that a communication should be sent to the Local Government Board to that effect. Dr. Benson moved an amendment believing that it would ill become him to allow such a resolution to pass without comment. He submitted that vaccination was not compulsory, inasmuch as the late Government in its wisdom had thought it fit and proper to give everybody a chance of avoiding vaccination by a conscience clause He failed, therefore, to see how vaccination could be said to be compulsory when everyone could claim exemption. But since the new Act was passed and the people were allowed to take advantage of the conscience clause more vaccinations had taken place throughout the country than before. According to a Parliamentary return they found that from Jan. 1st to June 30th, 1898, the number of vaccinations from different unions in England and Wales was 277,839, whereas in the corresponding six months of the next year there were 355,000, which were practically 70,000 more. There was an increase in the second six months. From July to December, 1898, they had 222,475, and in the second six months of 1899 313,797. Another paragraph stated that medical testimony could not be used as an argument in favour of vaccination. Now he disputed that altogether. If they would take a census of the medical profession they would find the profession generally in favour of vaccination It had been shown over and over again that when small-pox appeared in any place those who had been vaccinated successfully, and still more those who had been revaccinated, were not only less liable to take small-pox, but if they did take it the percentage of deaths was very much smaller than in those who had not been vaccinated at all The mortality among those who had been vaccinated varied from 1½ to 4 per cent, whereas the mortality of those who had not been vaccinated was at least 37 per cent If they undid what had been done in the last century, in time to come they would probably find small pox in the land as bad as before. As a matter of principle he proposed that the circular should lie on the table; there was no seconder, however, and the motion was passed. Resolutions of this kind have neither any influence on the Local Government Board nor on the general public. A proportion of guardians are disappointed with the number of persons who are sensible enough to protect their children against the scourge of small pox and also with regard to the cost. The cost, however, of an epidemic of small-pox is much greater.

"ABSENCE OF MIND" IN RAILWAY OFFICIALS

THE serious character of the recent railway accident at Slough, combined with the fact that the driver of the express train took upon himself the whole responsibility for the accident, has aroused an unusual degree of public interest in the catastrophe. This has been recently stimulated afresh by the report of Lieutenant-Colonel Yorke, one of the Board of Trade Inspectors. Such a report, seeing that it was admitted that the express train had run past two sets of signals which were against it, naturally discusses the cause of the failure on the part of the driver of the express to recognise that the signals were against him, as well as any remedies that may be available against such an accident in future The alternative explanations offered are that the driver was unconsciously drowsy, or that he suffered from the temporary inactivity of the faculties which we know as "absence of mind." The facts that he was 59 years of age and had been up since 5 A.M. are adduced in support of either view. And yet it is probably no unusual experience for a driver of an express train within two hours after mid-day to have been out of bed since five in the morning, and the age of 59 years is not one at which we expect to meet with a condition of senility. In reference to remedies available against the repetition of such accidents, the suggestion is made by Lieutenant-Colonel Yorke that all drivers, or at least those employed on express trains, should be examined by a medical man at the age of 55 years and in each succeeding year. We quite fail to see how such an examination is to be any protection. We venture to think that had Woolmar, the driver of the express on this occasion, been medically examined the day before the accident nothing much amiss could have been found in him, and even the most careful examination in similar cases may fail to reveal anything to justify the medical examiner in suspending the driver from work. It is a somewhat uncomfortable thought, but it is by no means unlikely, that an occasional driver or even a signalman may be subject to a temporary "absence of mind" which may be sufficient to imperil many lives and yet may be of such a character as to be undiscoverable by any kind of medical examination.

DRAINAGE BY-LAWS FOR LONDON.

AT the meeting of the council of the Sanitary Assurance Association, held at the offices, 5, Argyll-place, Regent-street, W., on Nov. 12th, Mr. Andrew Stirling in the chair, the new drainage by-laws, as drafted by the London County Council, were under consideration, and on the motion of Mr. William S. Hulsey, seconded by Dr. Edward H. Willoughby, the following resolution was passed:—

> That, in the opinion of the Council of the Sanitary Assurance Association the drainage by-laws proposed by the London County Council ought to be submitted to the new Metropolitan Borough Councils before they receive the force of law, and that the President of the Local Government Board be requested to submit the proposed by-laws to the said Councils before deciding as to their confirmation.

We have also received from Mr. Mark H. Judge a copy of a letter to be signed by metropolitan ratepayers and residents and to be presented to the Local Government Board. The letter refers to the well-known case which came up at Marlborough-street Police-court in April, 1899, in which a firm of contractors were summoned for having disregarded the by-laws of the London County Council. The contractors were fined £2 and costs, but neither the Council nor the vestry did anything more to enforce the law. The letter is signed by Mr. Judge and various co-signatories comprising prominent medical men and others interested in sanitation.

RUPTURE OF SPLENIC ANEURYSM DURING LABOUR.

ANEURYSM of the splenic artery is very rare. A remarkable case, reported by Mr. J. D. S. Nodes and Dr. F. Hinds of Worthing, was read by Dr. Spencer at the last meeting of the Obstetrical Society of London. The patient was 33 years old. Her fourth labour was perfectly normal and it lasted six hours; the placenta speedily followed the fœtus. Ten minutes later the nurse noticed that the patient's face became dark and a kind of convulsion set in with violent excitement. At length the patient turned pale, and she died in about a quarter of an hour. The coroner ordered a post-mortem examination to be held The peritoneal cavity was full of blood, chiefly fluid, and an aneurysm of the size of a grape was detected on the splenic artery; it had ruptured. The specimen, which was exhibited, is preserved in the museum of University College, London.

THE DISSOLUTION OF BONES BY BACTERIA.

IT is pretty certain that bacteria play an important part in the dissolution of bones, and if rapid dissolution is desired it follows that the bacteria should be afforded every opportunity of doing their work. This may have some bearing on our methods of the disposal of the dead. The action of bacteria is not likely to be facilitated by burying bodies at a comparatively considerable depth beneath the surface of the earth. Recent experiments have shown that when sifted bone-meal was inoculated with various bacteria and kept wet a remarkable resolution of the constituents of the bone, including the inorganic as well as the organic matters, took place. The organic matters resolved, as might be expected, into simpler compounds of the type of ammonia, but the most remarkable result consisted in the fact that the insoluble phosphate of lime was converted into soluble phosphoric acid. The experiments were confirmed in a practical way by manuring oats grown in large pots with bone meal and inoculating with different bacteria. The yield of oats was far greater when the bone meal was inoculated in this way. Several species of bacteria were employed with widely varying results. As a rule the organic substances which act as poisons in the human body are of a very complex nature, and as they are resolved into simpler ones their toxicity diminishes and finally disappears. In the putrefactive process the organisms concerned are rapidly breaking down complex toxic substances into simpler innocuous products. Bacteria, however, as in certain diseases, may elaborate poisons of a highly complex constitution, and thus we have two great classes of organisms from the point of view of the healthy human subject, the benevolent and the malevolent.

THE LATE PROFESSOR A. W. HUGHES.

THE Council of the University College, Cardiff, has resolved to establish an Alfred Hughes Memorial in connexion with the Medical School of the College. An influential committee is being formed and a meeting will be held on Nov. 24th, when it is hoped that all will attend who are interested in the establishment of a permanent record of Professor Hughes's great services to the College as its first professor of anatomy. The form which the memorial will take is to be decided upon at this meeting. Friends desirous of joining in the movement, if unable to attend the meeting, should communicate with Mr. J. Lynn Thomas, Mr. D. W. Evans, or the Dean of the Faculty of Medicine.

HISTORICAL SKETCH OF THE PLAGUE.

A MOST interesting historical survey of the plague has been published by Dr. P. Hauser under the title "La Peste dans les Temps Anciens et Modernes et son Avenir en Europe." It forms an extract from *La Médecine Moderne.* To those of our readers who are particularly interested in the history of the plague we can recommend a perusal of this volume, for they will find in it many instructive facts which are not to be found in the ordinary treatises on this subject. The little book consists of 114 pages divided into six chapters. The first consists of a general survey of the plague as it has been reported from early times. We learn that the first appearance of bubonic plague in Europe was in 543, and this outbreak is generally known under the name of "Peste Justinenne." The disease had been raging earlier than this in Lower Egypt and had even spread to Syria and Asia Minor, when it appeared at Constantinople at the date above mentioned. A pandemic form then rapidly obtained and with the highest mortality ever reported, for not only were large numbers of individuals attacked but 90 per cent. of those affected died. The plague disappeared from Europe in 1720 and no further outbreak was recorded until the second half of this century. In Chapter II. an account is given of the disease as it has appeared in Canton, Hong-Kong, and India in more modern times, and the results are added of the various scientific commissions which were appointed to study the extensive outbreak which occurred in Bombay. Chapter III. contains an account of the International Congress in Venice, the important results of which Dr. Hauser duly sums up. In Chapters IV. and V. the outbreaks at Alexandria and Oporto are described, especial stress being laid on the latter epidemic. The proceedings of the International Commission which met at Oporto to investigate the value of inoculation against plague are duly commented on and the conclusions arrived at by the Commissioners are recorded. The Commission recommended that the use of the vaccine should be encouraged as actively as possible, and its employment was particularly insisted on in the cases of those persons who were leaving an infected zone, and also in the cases of those who had frequently been in contact with victims of the malady The last chapter is occupied with a consideration of theoretical questions which have arisen from the re introduction of plague at Oporto in 1899, including certain points with regard to the bacteriology and epidemiology of the disease

DEATH IN THE VAT

DEATHS in the vat are by no means uncommon judging from the cases reported recently and within a comparatively short time In some instances, of course, a disaster arises through the deliberate negligence of the vat man, for instance, he may lean over the edge of the vat in endeavouring to control the contents, as with a stirrer, and over balancing himself may tumble into the liquid, and if he is not drowned or scalded he may be asphyxiated by carbonic acid or other gas, or the vat may contain poisonous fumes derived from a cleansing fluid or scavenging process which may overcome the workmen who may be lowered into its interior Occasionally a big explosion occurs in a vat as by the ignition of the vapour of alcohol in a whisky vat More recently it is reported that a man and a boy were employed to clean out a vinegar vat of 30 000 gallons capacity As it proved, they were simply lowered into a lethal chamber and were overcome by the fumes and killed When attempts at rescue were made one man very nearly lost his life and had to be immediately taken out It would appear, as we have said, from the accounts of occurrences of this sort which have come to our knowledge through the press that carelessness is particularly in evidence where vats are concerned And yet, on reflection, the most simple minded person must know that a vat is likely to contain dangerous vapours or gases The vat is commonly a receptacle in which a chemical process on a large scale, as, for example, fermentation, is going on, and consequently unbreathable if not toxic gaseous products are being evolved We have pointed out more than once in these columns that vats and all similar large receptacles should be thoroughly ventilated before an attempt to repair or to cleanse or to descend into them is made We should like to direct the attention of the Board of Trade to this matter and to ask them to consider whether the industrial processes connected with the use of vats should not be placed under some special regulations

THE medical profession in Newcastle has sustained a great loss by the death of Dr Dennis Embleton, in his ninety first year

THE autumn dinner of the Irish Medical Schools and Graduates' Association will take place at the Hotel Cecil on Wednesday, Nov 28th, at 7 15 o'clock, when the chair will be occupied by the President, Inspector General W. H Lloyd, M D St And, R N The guests of the evening will be General Sir William Olpherts V C, G C B, and Mr Alfred Percival Graves, the genial author of "Father O'Flynn" and other Irish songs

THE next general meeting of the Medico-Psychological Association of Great Britain and Ireland will be held on Nov 21st at 11, Chandos street W, commencing at 4 P M Papers will be read by Sir Dyce Duckworth, Dr G H Savage, and Dr Lewis Jones The last paper will be illustrated by electric apparatus and appliances, Members will dine together afterwards at the Café Royal at 8 P M

A LECTURE on 'Plague will be delivered in the Anatomical Theatre at the London Hospital Medical College on Thursday, Nov 22nd at four o clock, by Dr J Mitford Atkinson, principal civil medical officer at Hong Kong Members of the medical profession will be admitted on the presentation of their address cards

AT a meeting of the trustees of the Hunterian Collection held at the Royal College of Surgeons of England on Nov 9th, Sir Joseph Fayrer, Bart, K C S I, &c, was unanimously elected a trustee of the Collection to fill the vacancy occasioned by the decease of His Grace the Duke of Argyll, K G, K T

THE annual general meeting of the Anatomical Society of Great Britain and Ireland will be held at St Thomas's Hospital Medical School to day (Friday) at 4 30 P M A meeting of the Council will be held at the close of the general meeting

THE annual dinner of the Harveian Society of London will take place at the Café Monico on Thursday, Nov 29th at 7 P M Members intending to dine should communicate with the honorary secretary at 11, Wimpole street, W

THE death is announced of Mr R B Anderson, F R C S Eng, late of Tobago

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on Nov 6th, Dr. J ANDREW (President) being in the chair

Robert Miller Ronaldson, M D, M R C P Edin, was admitted by ballot to the Fellowship of the College

On a ballot the following candidates were admitted to the Membership of the College after examination William Wood, M B, C M Edin, George Pratt Yule, M D, C M Edin, South African Field Force; and Stuart McDonald, M B, C M Edin

The REGISTRAR reported that since the last quarterly meeting 41 persons had obtained the Licence of the College by examination

The SECRETARY reported that the arrangements with the magistrates and town council for the bacteriological examination of suspected products in respect of tuberculosis, diphtheria, and typhoid fever had now been completed

With regard to a letter from the Local Government Board for Scotland requesting the College to undertake the investigation of suspected plague products at the College laboratory it was resolved that the request be acceded to

By vote of the College the two following Licentiates were expelled from the College and deprived of their Licence—Frederick William Kirkham and Harman John Tarrant

PRESENTATIONS TO MEDICAL MEN —Mr Richard G Dick, M B, C M Glasg on the occasion of his leaving Burghead, Elgin, was recently presented by a few friends in that town and district with a purse of sovereigns sovereign case and matchbox combined, silver cigarette case watch appendages, and an illuminated address, in recognition of valuable services rendered by him during the severe epidemic among the children in 1887, as also of the work done by him since 1892 At the same time Mrs Dick was the recipient of a silver mounted oak tray —At the Great Western Railway Station Bath, on Nov 11th, the members of the ambulance class presented Mr A L Fuller, L R C P Lond M R C S Eng of that city with a traveller's writing desk as a token of appreciation of his gratuitous instructions to the class on first aid The deputy chairman of the railway company and other officials were present —At a recent meeting of the Willesden District Council the chairman, Mr J S Crone, L R C P Irel J P, was presented by his colleagues and officials with a handsomely designed solid silver cradle to commemorate the birth of a son during his term of office receiving his preliminary education in his native town he came to London and entered King's College. Here he gained many distinctions and prizes. Subsequently he was elected an Associate of the College. In 1866 he married a daughter of the late Lieutenant-Colonel W. Simonds and settled in practice at Blackheath. In 1893 he was as a Mason a Senior Grand Deacon of England. Dr. Gooding was until recently the senior member for Greenwich on the London County Council (1895 to 1898) and was vice-chairman of the Public Control Committee. He was the only coöpted poor-law guardian in the Greenwich district; was a late trustee of Roan's Charity; and was parish warden of Greenwich (1893 and 1894) and chairman of the Board of Governors and Directors of Poor (1893 and 1894). He was also a late commissioner of public baths and wash-houses (1893 to 1894), a commissioner of taxes for Blackheath division, and a member of the Greenwich Vestry and the Greenwich District Board of Works (1892 to 1894) and consulting surgeon to the Railway Passengers' Assurance Company.

Barnsley.—Mr. J. Fletcher Horne, M.D. St. And., F.R.C.S. Edin., F.R.S.E., is a justice of the peace for the Borough of Barnsley. Born at Barnsley, he was educated at the Leeds Grammar School, and later entered as a student at the Leeds School of Medicine, and qualified in 1874. He afterwards held the post of assistant medical officer at the Leeds General Infirmary. He commenced practice at Barnsley in 1876. He is senior surgeon to the Beckett Hospital and medical referee under the Workmen's Compensation Act for the district. In 1888 he won a seat on the school board, and in 1891 successfully competed for a seat on the town council which he still holds, and which has not been contested since. He was elected mayor on Nov. 9th by a unanimous vote. Dr. Horne has found time to dabble in literature. He has written a book on "Trephining in its Ancient and Modern Aspects (1894), whilst "The Mirage of Two Buried Cities," a beautiful and fascinating book dealing with the artistic and other remains of Herculaneum and Pompeii, was favourably reviewed in THE LANCET of March 17th of this year.

Dewsbury.—Mr. Robert Beattie (re-elected), M.D., M.Ch. R.U.I., after qualifying in 1876 went to Northleach, Gloucestershire, for a couple of years to assist Dr. Webb and was also assistant medical officer to the workhouse there. He was then at the Loughborough Infirmary and Dispensary as house surgeon for over two years. After this he entered on private practice in Canterbury, but only remained there a year or two. Over 15 years ago he went to Dewsbury. The sanitation and water-supply of that town have engaged his attention for many years and four years ago he entered the town council. Five years ago he was appointed medical officer of health to the Soothill Upper District Council and about the same time he was appointed honorary surgeon to the Dewsbury and District Infirmary. Quite recently he has been elected alderman and chairman of the Watch Committee.

Harrogate.—Mr. J. A. Myrtle (re-elected), M.D. Edin., J.P., late consulting physician to the Harrogate Bath Hospital, joined the town council three years ago, since which time he has advocated the purchase of the spa grounds at Harlow Moore and identified himself with other progressive municipal movements such as the extension of the electric lighting works.

Launceston.—Mr. W. Andrew, M.B., C.M. Edin., has been in practice since 1873 and has been a member of the town council for 22 years. He was elected mayor in 1885-86 and has been alderman for the borough and justice of the peace for 12 years.

Lostwithiel.—Mr. Robert Barclay-Allardice (re-elected) was born at Hamilton, Canada, and lived in the United States from 1850 to 1869. He the holds American degrees of M.A. and M.D. In 1898 he was elected a town councillor without opposition.

Ruthin.—Mr. J. Medwyn Hughes, M.B., C.M. Edin., has been appointed Mayor of Ruthin for the fifth time. He is an alderman and has been on the council for 12 years. He graduated M.B., C.M. Edin. in 1886, and has been in practice for 14 years. He was medical officer of health for Ruthin District for seven years, and he now fills the offices of union medical officer and public vaccinator. He has always taken an active interest in educational matters, both local and county.

Winchelsea.—Mr. John R. Skinner, M.B., C.M. Aberd., who has been in practice in the town for some nine years, was elected mayor of the Unreformed Borough on last Easter Monday.

CELEBRATION OF THE FOURTH ANNIVERSARY OF THE "LOCOMOTIVES ON HIGHWAYS" ACT.

UNDER the auspices of the Automobile Club of Great Britain and Ireland and in commemoration of the inauguration of the above Act (1896) a very successful tour was made on Nov. 10th in magnificent weather from London to Southsea, a distance of about 80 miles. The start was arranged to take place from the Horse Guards-avenue, Whitehall, at 9.30 A.M., and the motor-cars were timed to arrive at Portsmouth about five o'clock. Allowing for an interval for lunch at Godalming of three-quarters of an hour the time allowed for the whole distance of 80 miles was thus six hours, and three-quarters. This gives an average speed of 12 miles an hour. Of course, the actual speed attained sometimes exceeded this and sometimes it fell short of it. The ascent of the Hindhead was a feature of the tour, and there were some remarkable accomplishments up this famous "rise." The arrangements throughout were admirable and upwards of 100 motor-cars reached their destination without any serious breakdown and in less than the time allotted. The complete success of the "meet" was due in a large measure to the excellent injunctions drawn up by the committee and to the observance of them by the drivers in regard to certain precautions to be taken on the road. According to the rules of the club the speed of the motors was carefully to be moderated to eight miles an hour in passing through all the towns and villages, and within the villages passing on the off side at a speed exceeding eight miles an hour was prohibited. The drivers were also requested to observe every caution in turning corners and in passing through towns and villages, and "to show every consideration for other users of the road, especially those in charge of restive horses. . . . . The tour is in no sense a race, and as it is desired by its means to popularise motor vehicles drivers are besought to avoid driving at unlawful speeds." Again, it was enjoined that if any motors were used on Sunday drivers should sound motor horns as little as possible when passing places of worship during hours of service. We repeat that the strict observance of these excellent injunctions accounted for the complete success of the tour. It is the contravention of rules of this desirable kind that has brought motor-cars into a certain discredit, a discredit which need never have been incurred. Some amount of prejudice is bound to remain, but even this is giving way and on the occasion of this tour it was interesting and satisfactory to notice that here and there timid horses were brought out by coachmen and grooms to face the procession in order to accustom them to the horseless vehicles.

The greater number of the cars participating in the Southsea tour derived their motive power from petroleum spirit; a few were driven by electricity and a fair number by steam. Some improvement is undoubtedly being made in the direction of diminishing the noise and vibration of motor vehicles. Although most of the petroleum-driven motor cars are still noisy, yet earnest attempts have evidently been made to remove this reproach as well as the objectionable smell arising from the escape of unburnt oil. To some extent progress has been made in these important respects, but the steam-driven car must be given the palm, we think, in regard both to noise and smell. The steam motor car is as noiseless as a self-propelled vehicle can well be, while it is free from objectionable oily fumes. There is, however, a small escape of exhaust steam which doubtless with care could be avoided. The reduction in the number of cogs and chains in favour of cranks and rods would appear to give the steam motor car an advantage in respect of noise. Our impression, however, was that the oil-driven car required the least attention in the way of repairs or adjustment. It is a remarkable fact that three or four gallons of petroleum spirit are sufficient to take four persons in a six-horse power car a distance of 80 miles. Reckoning the cost of petroleum spirit at 10*d.* a gallon this would come out at about 9*d.* a head for the trip, or less than one-eighth of a penny per head per mile.

Public interest in the motor car does not subside, and it is probably only the great initial expense connected with it which militates against its becoming rapidly a universal means of travel The arrival of the cars at Portsmouth was heralded by a great and enthusiastic crowd of people The vehicles filed in single order past the Town-hall at a slow speed to enable the Mayor and his colleagues, who stood in a group at the foot of the steps, to inspect the vehicles A prize was awarded for that car which was deemed to be in the best condition after the run So called "non stop" diplomas were also awarded to those who completed the journey without a break, excepting, of course, the interval for luncheon These awards should be instructive in demonstrating the liabilities of a motor car to irregularities, break-downs, or detention from other causes incidental to a long run

THE WAR IN SOUTH AFRICA

IMPERIAL YEOMANRY HOSPITALS

A GENERAL meeting of the committee of the Imperial Yeomanry Hospitals Fund was held at 20, Curzon street, on Nov 8th, with the object of considering the question of prolonging the period during which the Yeomanry hospitals would remain in South Africa The Countess Howe presided and reported having received a letter from Lord Lansdowne, the Secretary of State for War, in which his lordship mentioned that Lord Roberts had expressed a strong desire that these hospitals should continue their valuable services until the return of the Yeomanry to England The report of the treasurer on the question of finance having been considered the committee assented to this request Friends and relatives of the members of the hospital staffs cannot, under these circumstances, hope to see them home at present It has, however, been found possible, in consequence of the diminution of serious surgical cases at Deelfontein, to dispense with the services of a few of the members of that staff, some of whom have already returned and others are *en route*, whilst a small percentage of the staffs of each of the branch *hospitals have* been invalided home

Lady Howe subsequently read a letter which she had received from Lady Roberts speaking in the highest possible terms of the work which is being done by the Yeomanry hospitals Amongst other things, Lady Roberts wrote ,—

> It has been a grand piece of work and you, the committee and the generous subscribers to the Yeomanry Hospital Fund, have earned the deep gratitude of all who have the welfare of soldiers at heart, be they Yeomen or regulars The Imperial Yeomanry Hospital at Deelfontein has done splendid work Since the Imperial Yeomenry Branch Hospital has been established here [Pretoria] all Yeomen who have been wounded or fallen sick near Pretoria or who have been brought in by train, have been taken straight there though there are still a few in other hospitals who had been taken to them before their own hospital was opened, and to whom it would have been a danger, or caused suffering to be moved I think you and the subscribers may rest assured that as far as circumstances and the well being of the patients would admit, the Imperial Yeomanry hospitals have been devoted to the service of the Yeomen

Lady Howe also read to the committee a communication which she had received from Colonel A T Sloggett, R A M C, enclosing a letter written to him by the resident magistrate at Richmond, S A This letter gave much satisfaction to the committee, as it proved that besides the good work which the hospital had been able to accomplish from a medical point of view the effect on the farmers in the surrounding district had been beneficial politically, and had produced a better feeling in the locality The letter ran as *follows* —

> SIR,—As there appears to be every probability of the Imperial Yeomanry Hospital at Deelfontein being shortly sent back to England, I take this opportunity, as civil commissioner and resident magistrate of the district of Richmond in which Deelfontein is situated, to express to you that in my opinion the establishment of the Imperial Yeomanry Hospital in this district has had a most beneficial effect upon the inhabitants in the neighbourhood All the farmers resident about Deelfontein are Dutch, and for some little time after the hospital was opened they kept aloof but I did all in my power to persuade them to visit the hospital and I am very glad to say that a very large number have done so and one and all have nothing but praise and good words to say about their visit They have always been received by you and your officers with every possible courtesy and have been entertained and shown round the hospital in a most friendly spirit and many of the Dutch farmers who for a long time held aloof regret not having sooner paid you a visit. The courtesy and friendly manner in which they have all been received has had a most excellent effect upon the farmers and I am of opinion if more opportunities could be found for our Dutch farmers to meet Englishmen in the same friendly spirit that they have been received at Deelfontein, it would materially assist in establishing a better feeling between the Dutch and English in South Africa than exists at present —I have the honour to be Sir, your obedient servant,
>
> GEORGE J BOYES Resident Magistrate.

It will be interesting to subscribers to know that up to the middle of October, the date of the last weekly reports received from the different principal medical officers, about 7000 sick and wounded had been successfully treated in these hospitals

THE IMPERIAL YEOMANRY FIELD HOSPITAL AND BEARER COMPANY

BY CHARLES STONHAM, F R C S ENG ,

CHIEF SURGEON AND OFFICER COMMANDING THE IMPERIAL YEOMANRY FIELD HOSPITAL, SENIOR SURGEON, WESTMINSTER HOSPITAL ETC

In my letter from Barberton[1] I *gave you a short outline* of our marches and work up to the time of our return to Pretoria from Springs on July 17th In this letter I propose to take you with us in our march to Balmoral back to Pretoria, and thence westwards to Rustenburg to the relief of General Baden Powell, and to bring you back to Pretoria again, and my next letter will carry you over the mountains to Barberton and, I hope, back with us to Pretoria

On July 17th, early in the morning, we entered Pretoria, sending our convoy to our old camping ground at Arcadia, and Major G E Hale, D S O, R A M C, and I went to report to the principal medical officer and to obtain further orders It was decided that we should leave a detachment of the field hospital and bearer company with some of our transport animals and wagons at Pretoria, while the main body marched to rejoin General Mahon's brigade We accordingly left Mr Openshaw and Dr Purves Stewart with 50 men, five wagons, and the necessary equipment and stores for the formation of a rest camp hospital, and the next morning we marched with the remainder to find General Mahon We came up with him in the afternoon at Kameelsdrift There had been two days' fighting here and we did not leave the ridge until the 20th, on which day we passed Pretorius's farm, and spent nearly all day in crossing the Pienaars river The drift was very steep and hence the wagons, and especially the heavy guns, required many teams to drag them over

These drifts are passages of the usually rocky beds of rivers, with comparatively little water at this season of the year During the rains there may be as much as 40 or 50 feet of water at the drifts, which are then consequently impassable Many drifts have very steep banks and abominable approaches, which, when a few wagons have passed over, are often a foot deep in mud and slush, in which carts sometimes stick and it becomes necessary to employ double, or even treble, spans of mules or oxen to pull them out I need hardly say that the passage of such drifts by ambulance wagons causes very considerable suffering to sick and wounded men, and delay to the whole convoy which *may extend for many miles On some days we have had to* pass as many as half a dozen drifts, our march being consequently slow and most arduous, not to mention the wear and tear to transport animals Drifts are a very severe test of the strength and durability of a wagon and in this respect we certainly have much reason to thank the builder of our wagons They are most excellent and they have stood the wear and tear admirably, and I think I may say that they are the best in the country Our ambulance wagons are built differently to those in use in the army, which only carry two patients lying down, whereas ours will take four and are much lighter

The following day at 8 30 A M —it is time after this digression to get on with our march—heavy firing was heard about 10 miles ahead of us, and it continued at intervals all day until we reached our camp where we found that the Boers had been shelling Colonel Hickman's force near a spruit Colonel Hickman with 800 men was camped here and on the next day he transferred our sick to his field hospital, which was going back to Pretoria On the 22nd, General Mahon's brigade joined General Ian Hamilton's division at Rustfontein where we remained the next day to give General Pole Carew and General Clery time to march up on our right flank Just before reaching camp at dusk I regret to say that one of our wagons came to grief in a hole, the native driver being killed and the wagon orderly receiving two very severe scalp-wounds

On the 24th we camped at *Bronkhorst Spruit, the enemy* sniping our rear during the march. Here we found a large force (about 20,000), Lord Roberts and Lord Kitchener having come up in the morning. The next day General Hamilton's division, of which our brigade was now a part, marched for Balmoral, 17 miles distant, but we were not destined to reach there without mishap. The weather had been very threatening all day and rain began about 2 P.M. About three miles on the wrong side of Balmoral our convoy was brought to a halt at a drift in which a Cape cart and a 4·7 gun had stuck; the former, however, was the offender so far as our further progress was concerned. By this time it was pitch dark, the rain was coming down in a pitiless torrent, and the wind was icy cold. To proceed was impossible and we had to stay there the night. Three miles of convoy in our rear was in the same plight—no food and no shelter. Major Hale with characteristic energy walked on to Balmoral to report, and on coming back wet through he and I made the best of it in a Cape cart which I had fortunately commandeered at Rustfontein. To describe this night is beyond my powers, but when I say that we alone lost 12 mules and that I counted 195 dead animals within quite a short distance some idea may be formed as to its severity. Early in the morning we made ready to proceed, when we heard that an officer of the Argyll and Sutherland Highlanders had died in the night from exposure. We sent back a stretcher party and carried the body in with us to be buried by the regiment. We reached Balmoral at 10.30 A.M. and looked forward to a day's rest, but we were doomed to disappointment, as orders came at 11 o'clock for us to march at 12.30 back to Pretoria. Many guesses were made as to the reason for the division's return, and we thought that we were being done out of the final advance to Komati Poort and neighbouring district, but events proved that this was yet far distant, important work having to be done in the Rustenberg district before the final advance could be undertaken. Our return march was uneventful. We reached Pretoria on July 30th, and the division marched past Lord Roberts and a large crowd of people at 12 o'clock on its way to Daspoort, two miles to the west of the town. We sent all our sick, who were suffering chiefly from fever and intestinal trouble, to the detachment, and the next morning I went down and found that the detachment had been installed by the principal medical officer in a house which they were energetically preparing as a military hospital. This was taken over by the Royal Army Medical Corps, our officers and men being lent for the use of the hospital until we should require their services in the field. Unfortunately, our mules had been handed back to the transport, and hence we could not obtain fresh animals. This day was a very busy one in Pretoria as we were under orders to march the next morning.

---

[1] THE LANCET Nov 10th, 1900 p 1372.

On August 1st, General Mahon's brigade marched through Wonderboom Pass and then westwards on the Rustenburg road. Pilcher was on our right and the rest of General Hamilton's division were on the left, separated from us by the range of hills. At 8 A.M. fighting began and continued all day, our guns dislodging the Boers from a kop at Middlewater where we camped for the night. Two of our ambulances went out after the fighting and brought back five wounded men, all suffering from flesh wounds of the thighs and buttocks inflicted as they were lying down. We finished dressing these cases by 10 P.M. and sent one of our ambulance wagons with the wounded back to Pretoria on the next morning. The next day we marched forward, heavy firing proceeding all day from Hamilton's direction, but General Mahon's brigade did not come into action. In the evening we camped at Zilikatz Nek (or Nitrals Nek), where the Lincolns had been attacked some time before. The fighting to-day had been with a commando holding this pass and Hamilton had about 40 casualties which were dealt with by his own field hospitals.

The country we were now in was very pretty; certainly it might be called the garden of the Transvaal. The valley is bounded by considerable hills on either side and is very fertile and studded by prosperous farms which in many cases are well stocked. Oranges, lemons, and similar fruits grow
and proved most acceptable, for the want of
s and fruit is very severely felt after a time
s are eagerly taken when a chance offers.
r march was a very short one, as we
the Crocodile river by a bad drift.

were brought in from neighbouring farms. The next day we marched to Sterkstroom, and a runner came in from General Baden-Powell who was hemmed in at Rustenburg. The messenger brought a map made by the general indicating the various positions occupied by the Boers and their numbers. When we advanced on the 5th, however, the enemy were not to be found and we reached Rustenburg unopposed. The country on this side of Pretoria is naturally fortified, and if the Boers do not defend it it argues most strongly that they will not again stand. On the 6th Major Hale and I marched out with part of our ambulances to proceed towards Magata Pass, where the enemy were said to be in force, but we returned at night without having seen anything of them, although heavy gun firing was heard all day some miles distant, and it was feared that the Boers had captured one of our convoys coming up from Mafeking. The next day we marched back, as we thought, for Pretoria, having relieved Rustenburg, and General Baden-Powell marched with us. We carried in our wagons all the sick and wounded who were fit to leave the Rustenburg Hospital and we supplied the medical officer in charge of those who could not be moved with medical comforts from our own stores. On the 9th we passed over Commando Pass and camped at Groot Platz, from which place we sent a sick convoy to Pretoria. On the 11th we again proceeded westwards, passing through Heckpoort the next day and camping at Thorndale. On the 13th Major Hale and Dr. Green, with two ambulance wagons, went on with a flying column under General Mahon, the rest of us following with the remainder of the division. We came in touch with Lord Kitchener and Lord Methuen on August 15th. These generals were pursuing a commando under Christian de Wet who was making for Rustenburg to join Delarey. Mahon's column came back to our camp to-day.

On the 17th, having camped the night before five miles to the westward, we moved on to Olifant's Nek, half a battery and some infantry going on ahead with four of our ambulances under Major Hale. After some shelling the Boers were driven from the Nek and we proceeded on to Rustenburg. From this action we had only two wounded. The next morning we again left Rustenburg and marched towards the Crocodile river, near which, at Zwartkopjes (or Roodekopjes), General Mahon's brigade had a two days' action on August 19th and 20th with De Wet's commando. On the first day one of our wagons, together with an Australian ambulance, was taken by the Boers, but Major Hale rode back and represented the facts to the general who at once sent a medical officer from one of the Boer ambulances which was in our lines and which we had helped with drugs and medical comforts to interview the Boer commandant, with the result that the ambulance came in later in the afternoon and brought in some wounded. On the night of the 20th the Boers vacated their position and we went in pursuit as far as Warm Baths but failed to come up with them. This was on August 24th. On August 26th we left for Pretoria where we arrived on the 28th, to leave again, however, after one day's rest for our march to Barberton.

The Devil's Kantoor, Oct. 6th.

PROFESSOR CALMETTE ON ANTI-PLAGUE SERUM-THERAPY.

IN the course of the second Harben Lecture, delivered at the Examination Hall of the Royal Colleges of Physicians of London and Surgeons of England on Nov. 14th, Professor A. CALMETTE, Director of the Pasteur Institute at Lille, said that certain epidemics of plague had been remarkable for the fact that all the cases presented a primitive pneumonic form, the mode of entry having been, therefore, exclusively through the nose or mouth, while in others the infection had been produced by the skin, either following slight excoriations or bites of fleas, bugs, and other parasitical insects. During the epidemic in Portugal last year he observed with Salimbeni a case in which the infection was through a bug-bite. Hankin and Simond, in India, had cited several examples of individuals who had contracted plague from touching diseased or dead rats.

It was probable that the transmission of the plague to the man was by fleas living on the rats. Experiment in the laboratory had shown how quickly a healthy rat would contract the plague if caged with a diseased rat which was infested with fleas, while a healthy rat remained healthy when shut up with one which was diseased but was free from fleas. Whatever the mode of entry of the virus, multiplication of the plague bacillus resulted first in the lymphatic channels and then in the blood. By experiments on animals in the laboratory it had been proved that even at a few hours after the infection plague bacilli were to be found in the blood and that in consequence these bacilli existed in immense quantities in all the organs. The effect of an injection of the serum should be to provoke rapid destruction of all the plague bacilli by phagocytosis. The slow absorption of the serum injected by the subcutaneous method hardly attained this end, particularly if the quantity of serum injected was not considerable. The result of this was that, the organism not being at once impregnated with the active substance, some of the bacilli escaped from the phagocytic action and those which escaped were submitted feebly to the action of the serum, became accustomed to it, and finally resisted its influence entirely. After a time of reaction more or less long, the duration of which depended on the quantity of microbes destroyed by the phagocytes which had undergone the action of the serum, the infection took its course and the serum was powerless to check it. These results were quite different if the serum instead of being introduced beneath the skin were injected as soon after the commencement of the disease as possible straight into the veins. When the plague bacillus was discovered in 1894, and the first cultures were received from Yersin in Europe, Professor Calmette and Professor Borrel tried by vaccinating animals to obtain a plague toxin and a serum as an antidote. Their first attempts to isolate the cultures in bouillon not being satisfactory they succeeded with great difficulty in obtaining toxins free from living microbes which would kill mice by a strong dose of 1·50 to the cubic centimetre. They vaccinated small animals in the laboratory—rabbits and guinea-pigs—by means of virulent cultures killed by exposure for one hour to 70° C. It being possible to strengthen the artificial immunity of animals by vaccinating them by means of repeated inoculations with virulent plague bacilli, experience showed that a serum could be obtained capable of anticipating the plague or arresting the infection and that mice showing extreme sensibility to the plague bacillus could easily be preserved by inoculating them 15 or 16 hours after the virus with a sufficient dose of serum from a vaccinated animal. These experiments showed that it was possible in this manner to arrest the plague in advanced stages in monkeys and rabbits. Almost immediately upon the introduction of the serum into the general circulation an intense phagocytosis of the plague bacilli was produced; in a few hours they were swallowed up in the leucocytic cells, and it was not long before they disappeared completely and the animal was cured. In the human being the healing process after the intravenous injection of serum was absolutely identical with this. The temperature dropped four or five hours after the injection; it rose again for eight or 12 hours after, and then finally dropped. This temporary rise following the injection corresponded with the period during which the plague bacilli disappeared from the circulation and were swallowed up by the leucocytes. It must be laid down that a medical man confronted with a case of plague must therefore immediately inject 20 cubic centimetres of anti-plague serum into a superficial vein. If the fever had not subsided completely after 24 hours, and if the diagnosis had been confirmed bacteriologically, the injection must be renewed. No one need be afraid of performing these intravenous injections if care were taken to inject gently and to introduce into the blood neither air-bubbles nor solid matter. For this reason no serum should be used except anti-plague serum preserved without the addition of any antiseptic substance and kept simply from deterioration by being heated for an hour three times a day at 58° C. If the serum contained suspended solid matter it must be carefully filtered through a piece of fine linen which had been previously boiled. The most convenient veins to choose for these intravenous injections were the superficial veins of the dorsal surface of the hand or the palmar surface of the wrist. The preventive injection should be made under the skin of the abdomen in a dose of 10 cubic centimetre. Incidental symptoms common to all horse serums were very transitory and not at all serious and were indeed exceptional with serums heated to 58° C.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6485 births and 3755 deaths were registered during the week ending Nov. 10th. The annual rate of mortality in these towns, which had been 17·3 and 17·6 per 1000 in the two preceding weeks, declined again to 16·9 last week. In London the death-rate was 17·0 per 1000, while it averaged 16·8 in the 32 provincial towns. The lowest death-rates in these towns were 11·1 in Birkenhead, 11·8 in Norwich, 11·9 in Leicester, and 12·1 in Cardiff; the highest rates were 20·4 in Liverpool, 21·6 in Sunderland, 22·5 in Manchester, and 26·0 in Salford. The 3755 deaths in these towns included 356 which were referred to the principal zymotic diseases, against 485 and 425 in the two preceding weeks; of these, 88 resulted from diphtheria, 75 from diarrhœa, 70 from "fever" (principally enteric), 50 from measles, 43 from whooping-cough, and 30 from scarlet fever. No fatal cases of any of these diseases occurred last week in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Brighton, Cardiff, Oldham, and Halifax, and the highest rates in Wolverhampton, Blackburn, Sheffield, and Sunderland. The greatest mortality from measles occurred in Swansea; from whooping cough in Derby; from "fever" in Portsmouth, Wolverhampton, and Derby; and from diarrhœa in Blackburn, Sunderland, and Gateshead. The mortality from scarlet fever showed no marked excess in any of the 33 towns. The 88 deaths from diphtheria included 35 in London, seven in West Ham, seven in Sheffield, five in Bristol, five in Leicester, and five in Liverpool. No fatal case of small-pox was registered last week in any of the 33 towns; and no small-pox patients were under treatment in the Metropolitan Asylums hospitals on Saturday last, Nov. 10th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2702, against numbers increasing from 1703 to 2619 on the 10 preceding Saturdays; 289 new cases were admitted during the week, against 327, 320, and 336 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had risen from 164 to 268 in the five preceding weeks, further rose last week to 307, but were 85 below the corrected average. The causes of 57, or 1·5 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Cardiff, Oldham, Newcastle, and eight other smaller towns; the largest proportions of uncertified deaths were registered in Bristol, Liverpool, Preston, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·6 per 1000 in each of the two preceding weeks, declined to 19·2 per 1000 in the week ending Nov. 10th, but was 2·3 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·0 in Aberdeen and 16·6 in Paisley to 20·3 in Glasgow and 24·2 in Dundee. The 594 deaths in these towns included 22 which were referred to whooping cough, 17 to diarrhœa, seven to diphtheria, seven to "fever," five to measles, and four to scarlet fever. In all, 62 deaths resulted from these principal zymotic diseases, against 67 and 77 in the two preceding weeks. These 62 deaths were equal to an annual rate of 2·0 per 1000, which was 0·4 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping cough, which had increased from 13 to 18 in the four preceding weeks, further rose last week to 22, of which 16 occurred in Glasgow and four in Dundee. The deaths from diarrhœa, which had decreased from 53 to 24 in the five preceding weeks, further declined to 17 last week, and included nine in Glasgow and six in Dundee. The fatal cases of diphtheria, which had been six and seven in the two preceding weeks, were again seven last week, of which three were registered in Glasgow, two in Edinburgh, and two in Leith. The deaths referred to different forms of "fever," which had been four and 12 in the two preceding weeks, declined again to seven last week and included four in Glasgow. The fatal cases of measles, which had been two, four, and eight in the three preceding weeks, declined again last week to five, of which three were recorded in Edinburgh and two in Aberdeen. The deaths from scarlet fever, which had been eight in each of the two preceding weeks, declined to four last week, and included three in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 98 to 148 in the five preceding weeks, further rose last week to 150, and showed an excess of 32 over the number in the corresponding period of last year. The causes of 24, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·0 and 21·9 per 1000 in the two preceding weeks, further rose to 22·5 per 1000 during the week ending Nov. 10th. During the past four weeks the death-rate in the city has averaged 22·3 per 1000, the rate during the same period being 16·4 in London and 15·9 in Edinburgh. The 151 deaths belonging to Dublin registered during the week under notice were 4 in excess of the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 12 and 13 in the two preceding weeks; of these, six resulted from diarrhœa, four from "fever," and one from whooping-cough. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·5 in London and 1·4 in Edinburgh. The fatal cases of diarrhœa, which had been nine, six, and five in the three preceding weeks, rose again to six last week. The deaths referred to different forms of "fever," which had been five, four, and three in the three preceding weeks, rose again last week to four. The mortality from whooping-cough showed a decline from that recorded in recent weeks. The 151 deaths in Dublin last week included 31 of infants under one year of age and 37 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons slightly exceeded the numbers in the preceding week. Six inquest cases and six deaths from violence were registered, and 49, or nearly one-third, of the deaths occurred in public institutions. The causes of 12, or nearly 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1900.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 10·7 per 1000 of the population, estimated at 4,589,129 persons in the middle of the year. In the three preceding months the rates had been 7·0, 6·0, and 8·7 per 1000 respectively. The rates were considerably below the average in St George Hanover-square, Westminster, St. Martin-in-the-Fields, St. Luke, St. Olave Southwark, and Wandsworth; while they showed the largest excess in Fulham, Stoke Newington, Strand, Limehouse, Poplar, and St. George Southwark sanitary areas. One case of small-pox was notified last month in Islington, but not one in any other sanitary area; there were no new cases admitted into the Metropolitan Asylums hospitals last month, and only one small-pox patient remained under treatment on Saturday, Nov. 3rd. The prevalence of scarlet fever showed a large increase over that recorded in the preceding month; among the various sanitary areas this disease was proportionally most prevalent in Hammersmith, Fulham, Strand, City of London, St. George Southwark, and Lewisham (excluding Penge). The Metropolitan Asylums hospitals contained 2569 scarlet fever patients at the end of October, against 1804, 1657, and 1899 at the end of the three preceding months; the weekly admissions averaged 314, against 210, 152, and 255 in the three preceding months. The prevalence of diphtheria showed a considerable increase over that recorded in the preceding month; the greatest proportional prevalence of this disease occurred in Fulham, Hampstead, Stoke Newington, Poplar, Bermondsey, and Camberwell sanitary areas There were 1458 diphtheria patients in the Metropolitan Asylums hospitals at the end of October, against 1256, 1171, and 1231 at the end of the three preceding months; the weekly admissions averaged 206, against 183, 142, and 185 in the three preceding months. The prevalence of enteric fever was slightly in excess of that recorded in the preceding month; among the various sanitary areas this disease was proportionally most prevalent in St. Martin-in-the-Fields, Limehouse, Poplar, St. Saviour Southwark, St. George Southwark, and Bermondsey. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 129, 170, and 329 at the end of the three preceding months, had further risen to 444 at the end of October; the weekly admissions averaged 61, against 20, 32, and 69 in the three preceding months. Erysipelas was proportionally most prevalent in Holborn, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, and Mile End Old Town sanitary areas. The 33 cases of puerperal fever included five in Islington, four in Mile End Old Town, three in Hackney, and three in Wandsworth sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Nov. 3rd the deaths of 6749 persons belonging to London were registered, equal to an annual rate of 15·3 per 1000, against 15·7, 19·4, and 16·5 per 1000 in the three preceding months. The lowest death-rates last month in the various sanitary areas were 8 8 in Stoke Newington, 9 6 in Hampstead, 11·6 in St. George Hanover-square, 11·7 in Paddington, 11·8 in Wandsworth, and 12·3 in Hammersmith and in St. Martin-in-the-Fields; the highest rates were 21·7 in St. George Southwark, 21·8 in Holborn, 22·1 in St. Luke, 22·3 in Limehouse, 23·2 in St. Saviour Southwark, and 24·3 in St. George-in-the-East. During the five weeks of October 763 deaths were referred to the principal zymotic diseases; of these, 53 resulted from measles, 47 from scarlet fever, 170 from diphtheria, 96 from whooping-cough, 95 from enteric fever, and 302 from diarrhœa. The lowest death-rates from these diseases last month occurred in Paddington, St. George Hanover-square, Westminster, St. James Westminster, St. Martin-in-the-Fields, Whitechapel, St. Olave Southwark, and Woolwich; and the highest rates in Fulham, Limehouse, Poplar, St. Saviour Southwark, St. George Southwark, Newington, and Bermondsey. The 53 deaths from measles showed a decline of 94 from the corrected average; this disease was proportionally most fatal in Clerkenwell, Shoreditch, Limehouse, St. Saviour Southwark, St. George Southwark, and Bermondsey sanitary areas. The 47 fatal cases of scarlet fever showed a decline of 55 from the average number in the corresponding periods of the 10 preceding years; the greatest proportional mortality from this disease occurred in St. Giles, Holborn, City of London, Limehouse, St. George Southwark, and Rotherhithe. The 170 deaths from diphtheria were 99 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Fulham, Hampstead, Mile End Old Town, Poplar, Bermondsey, and Lee. The 96 fatal cases of whooping-cough were equal to the corrected average in the corresponding periods of the 10 preceding years; this disease showed the highest proportional fatality in Marylebone, St. Pancras, St. Giles, St. George-in-the-East, Limehouse, and Newington. The 95 deaths referred to enteric fever showed a decline of seven from the corrected average; among the various sanitary areas the death-rate from this disease was highest in Hammersmith, St. George Hanover-square, Hackney, Mile End Old Town, St. George Southwark, and Newington sanitary areas. The 302 fatal cases of diarrhœa were 84 above the average number in the corresponding periods of the 10 preceding years; this disease was proportionally most fatal in Bethnal Green, Limehouse, Poplar, St. Saviour Southwark, St. George Southwark, and Rotherhithe. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during October was nearly 18 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 148 per 1000. The lowest rates of infant mortality were recorded in Paddington, Hammersmith, Marylebone, Stoke Newington, St. Olave Southwark, and Plumstead; and the highest rates in Strand, Bethnal Green, St. George-in-the-East, Limehouse, St. Saviour Southwark, and Lee sanitary areas.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING OCTOBER, 1900.

(Specially compiled for THE LANCET.*)*

SANITARY AREAS.	Estimated population in the middle of 1900.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small pox.	Measles.	Scarlet fever.	Diphtheria.‡	Whooping cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

† Bubonic disease.

‡ Including deaths from membranous croup.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon R. L. Price to the *Vivid*. Civil Practitioner W. H. C. Davey to be Surgeon and Agent at Liverpool.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel H. J. Robbins, A.M.S. (retired), has handed over the medical charge of Station Hospital, &c., Golden Hill Fort to Civil Surgeon A. R. Walters, and assumed charge of the troops and Station Hospital at Parkhurst. Captain F. Dove has been granted an extension of leave to Feb. 2nd, 1901, for the recovery of his health.

VOLUNTEER CORPS.

Royal Engineers: 1st Devonshire and Somersetshire: The undermentioned officer resigns his commission:—Surgeon-Lieutenant H. P. V. Wiggin.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Walter Whitehead to be Honorary Surgeon-Colonel on appointment as Honorary Commandant.

TRANSVAAL WAR NOTES.

Mr. Charles Baehler, general manager of the Ghézireh Palace and Shepheard's Hotels in Cairo, has placed gratuitously at the disposal of the Duke of Abercorn's Sick and Wounded Officers' Committee accommodation in these hotels for two married officers and their wives and for four single officers.

Major J. G. Black, R.A.M.C., reported to be dangerously ill at Newcastle from enteric fever, is improving. Lieutenant E. B. Knox, R.A.M.C., is dangerously ill at Pretoria.

The *Times* states that Surgeon-General Stephenson, R.A.M.C. Colonel T. J. Gallwey, R.A.M.C., and Major W. Babtie, R.A.M.C., V.C., are on their way home to England in the *Tantallon Castle.*

CAMP SANITATION IN SOUTH AFRICA.

The *Times* of Nov 13th contains a very good
sensible letter from a regimental officer on "Camp Sa
tion," which, if it contains nothing particularly
has much that is practical and true, hitting of
points that are apt to be overlooked or insu
attended to in camps. The great difficulty
of war does not, however, always arise so m
ignorance of the elementary principles of ar
on the part of those concerned as from th

referred to the principal zymotic
resulted from measles, 47 from scarlet
eria, 96 from whooping-cough, 95 from
02 from diarrhœa. The lowest death-
iseases last month occurred in Padding-
Hanover-square, Westminster, St. James
St. Martin-in-the-Fields, Whitechapel, St.
ark, and Woolwich; and the highest rates
Limehouse, Poplar, St. Saviour Southwark,
Southwark, Newington, and Bermondsey.
eaths from measles showed a decline of 94
corrected average; this disease was proportion-
t fatal in Clerkenwell, Shoreditch, Lime-
. Saviour Southwark, St. George Southwark, and
sey sanitary areas. The 47 fatal cases of scarlet
showed a decline of 55 from the average number
e corresponding periods of the 10 preceding years;
greatest proportional mortality from this disease
urred in St. Giles, Holborn, City of London, Lime-
ouse, St. George Southwark, and Rotherhithe. The 170 deaths from diphtheria were 99 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Fulham, Hampstead, Mile End Old Town, Poplar, Bermondsey, and Lee. The 96 fatal cases of whooping-cough were equal to the corrected average in the corresponding periods of the 10 preceding years; this disease showed the highest proportional fatality in Marylebone, St. Pancras, St. Giles, St. George-in-the-East, Limehouse, and Newington. The 95 deaths referred to enteric fever showed a decline of seven from the corrected average; among the various sanitary areas the death-rate from this disease was highest in Hammersmith, St. George Hanover-square, Hackney, Mile End Old Town, St George Southwark, and Newington sanitary areas. The 302 fatal cases of diarrhœa were 84 above the average number in the corresponding periods of the 10 preceding years; this disease was proportionally most fatal in Bethnal Green, Limehouse, Poplar, St. Saviour Southwark, St. George Southwark, and Rotherhithe. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during October was nearly 18 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 148 per 1000. The lowest rates of infant mortality were recorded in Paddington, Hammersmith, Marylebone, Stoke Newington, St. Olave Southwark, and Plumstead; and the highest rates in Strand,
al Green, St. George-in-the-East, Limehouse, St.
wark, and Lee sanitary areas.

DEATHS FROM PRINCIPAL INFECTIOUS DISEA

SANITARY AREAS.	Small pox.	Measles.	Scarlet fever	Diphtheria †	Whooping cough	Typhus fever.	Enteric fever.	Other continued fevers.
LONDON	—	53	47	170	96	—	9	

desquamated freely on the fourteenth day. On Nov. 21st (18 days after the solitary case of scarlet fever had been isolated) I saw the first two boys who complained of headache, sore-throat, and general malaise. The boys looked and felt ill, and I had them removed to our sanatorium for observation. These two cases were followed by the remaining cases within the next three days. I will select the case of the most typical as the features were common to all. This boy sickened on Nov. 23rd complaining of malaise and sore-throat. The patient looked ill and pale and on taking his temperature it was found to be 100°F. The throat was injected, especially the faucial arch, and the tonsils were swollen; the tongue was red and moist; his conjunctivæ were not injected, there was no coryza, and his pulse was quiet at 84. Deeming the case suspicious I had him removed to the sanatorium where I saw him next day. He was then about the same but had vomited during the night. On Nov. 26th he was worse, the throat was more painful, and the tonsils had follicular patches on them. There was a well-marked rash on the soft palate. The temperature was 101·4°. On his arms and chest was a small darkish-red punctiform rash exactly resembling that of scarlet fever. *The lymphatic glands were not enlarged,* and more especially I noted that the post-auricular glands were not enlarged as they usually are in rose rash. The following day he was better and the rash was fading, and the temperature was 100°. From that day he rapidly got well, and all his symptoms diappeared until he became convalescent on Nov. 27th. I quite expected him to peel, but although I kept him under close observation for another 14 days no sign of desquamation was visible and he returned to school on Dec 11th. These cases appear to be exactly what Dr. Clement Dukes has described as "the fourth disease," and which he admits he diagnosed (as I did) as the scarlatinal variety of rose rash, the chief discrepancies between the two diseases being, so far as my cases are concerned, *(a) the different colour of the rash, and (b) the fact* that there was neither coryza nor any enlargement of the post-auricular glands—this latter symptom I have noted in
per cent of the rose rash cases which I have treated.
e most striking difference between my cases and a
al scarlet fever was the fact that there was no
amation at all. So far as I can tell the infection
asted for a shortish period, certainly under 21 days,
boys returned to school on the eighteenth day and
further cases. The chief interest in this series of
in the fact that here we had to deal with an
f some disease which was neither rose rash nor
, and the only rational explanation is that there
"fourth disease."

I am, Sirs, yours faithfully,

R. LESLIE ROMER

fortnight was over I could come
n that Dr. Dukes had very skil-
tangled this group of cases from
t and rubella on the other. The
ith this view, for the boys mixed
ion, with others after three weeks,
ith their young brother, aged three
en of others was known to take place.
, unless very extensive, may not prove
is single experience, itself in keeping with

others of this series, suggests as likely one of the following alternatives: on the one hand, that these were cases of this mild "fourth disease"; and on the other, that they were cases of mild scarlet fever, but that on the latter supposition the duration of the infectiousness of scarlet fever is much shorter than is usually held to be the case. This is a view which seems to have struck a good many observers of scarlet fever.

May I add a few observations upon the infectiousness of rubella? We are told of this curious complaint, with its five or six names and its period of incubation varying from five to 21 days, that it is highly infectious. In regard to this point one may fairly ask how it can ever be proved that a complaint with such a range of incubation is infectious at all and is not rather connected with some seasonal change operating upon a group of persons similarly circumstanced. With all the evidence from large outbreaks this is obviously going too far, but I would submit that the limitations of the infectiousness of rubella are greater and more numerous than those of any known infectious disease. As a fact, until a small outbreak of rubella took place this year in this neighbourhood, I could only remember one case of this complaint which *appeared* to spread from one person to another in a family, and that is during some 20 years of general practice. This, again, is only negative evidence and not extensive, but such experiences demand some attention. I would suggest the following propositions as to the infectiousness of rubella. First, that the infectiousness is less than that of any known infectious disease. Secondly, that it is limited very much to young adults and schools, avoiding children and grown-up persons. Thirdly, that its infectiousness is limited by season. I am, Sirs, yours faithfully,

Blackheath, Nov. 14th, 1900. WALTER KIDD, M.D. Lond.

THE DIAZO-REACTION IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—In an address delivered by Dr. James Barr on the Treatment of Typhoid Fever reported in THE LANCET of Sept 29th, 1900 (p. 919), there occurs the following sentence: "As a very early test I prefer Ehrlich's diazo-reaction of the urine which, although present in some other febrile affections, is never so pronounced as in typhoid fever" If Dr. Barr will refer to the *Indian Medical Gazette* for June, 1893, he will find recorded some experiments which show that there are other diseases in which the "diazo" reaction is quite as well marked as in any case of typhoid fever. I am sorry I have not a spare copy of the paper to send you. I am, Sirs, yours faithfully,

J. H TULL WALSH, Major I.M.S.

Berhampur, Bengal, Oct. 21st, 1900.

"THE SMOKE NUISANCE."

To the Editors of THE LANCET.

SIRS,—Once more I feel that I must trespass upon your valuable space on account of the statement made by the honorary treasurer of the Coal Smoke Abatement Society in your columns[1] that—

> The principal difficulty in the society instituting proceedings is that the society would have to prove in court a nuisance by the smoke, a not always easy thing to prove to the satisfaction of a magistrate, whereas if the vestry prosecutes it only has to prove that black smoke was emitted, which under Section 23 and 24 constitutes a nuisance.

I must again point out that under Section 23 the non-consumption of smoke is a specific offence and legal proceedings for penalties can only be instituted by the sanitary authority. The actual question of a nuisance does not arise under Section 23, but under Section 24 "...... sending forth black smoke in such quantity as to be a nuisance; shall be nuisances liable to be dealt with summarily under this Act"; therefore I fail to understand why the honorary treasurer of the Coal Smoke Abatement Society writes that a sanitary authority under Section 24 has not to prove that which a private individual has to prove when proceedings are taken by him under Section 12 I must also point out that where a chimney, not belonging to a private house, sends forth black smoke so as to be a nuisance, it is not necessary in proceedings to abate it to prove that the smoke is injurious to health (Gaskell *v.* Bayley 80 L.T. (N S) 516). Might I suggest to any person aggrieved through the emission of black smoke that snap-shots be taken of the offending shaft to be produced in a court of summary jurisdiction? I am, Sirs, yours faithfully,

FREDERICK WILLIAM ALEXANDER,
Medical Officer of Health, Poplar and Bromley.

Bow-road, Bow, E, Oct. 24th, 1900.

SNOW BLINDNESS.

To the Editors of THE LANCET.

SIRS,—A friend of mine who spent his holiday this summer in Switzerland suffered whilst there from an attack of snow blindness. The first symptom which he noticed was the presence of a rainbow surrounding the candle in his bedroom. I shall be glad to know if this is a common or known symptom; and, further, I shall be obliged if any of your readers can inform me what is the optical explanation of similar rainbows in glaucoma.

I am, Sirs, yours faithfully,

Llandudno, Nov. 10th, 1900. EDWARD GOODDY.

*** The rainbow surrounding the flame of a candle in the case referred to by Mr. Gooddy was probably due to some disturbance of the epithelium of the cornea consequent upon exposure to cold and glare. These conditions are acknowledged by all travellers in the Arctic Regions to set up severe conjunctivitis. The Esquimaux use protectors made with narrow slits to minimise the effects of such exposure. The haloes observed as a subjective phenomenon in glaucoma are the results of similar conjunctival trouble proceeding from increased tension of the globe. A halo of the same kind is seen on looking at a flame through a glass that has been breathed upon or that is frosted on one side.—ED. L.

THE TEACHING OF ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—Having been on the staff of a provincial hospital for nearly 20 years I have had many opportunities of observing the knowledge possessed by such recently qualified men as seek for hospital appointments. I have no hesitation in saying that the majority of them are imperfectly trained and some are lamentably ignorant in that important branch of their profession, the administration of anæsthetics. If the candidates for hospital appointments, who are generally above the average and as a rule only secure their appointments after severe competition, are deficient, the rank-and-file must be deplorably incompetent. I freely admit that I have met with notable exceptions, but I maintain that if the education was more thorough they would all be efficient, or at any rate they would not be so grossly ignorant as I have found them. For instance, I have seen men apply the facepiece of Clover's inhaler upside down. Others have commenced with the ether full on and others have admitted that they never saw the inhaler before. I have waited three-quarters of an hour while a man was endeavouring to place a patient under the influence of chloroform, and in the administration of gas I have generally had to act as instructor. Most of the men indulge in unlimited poking of their fingers into the poor patients' eyes and are generally fussy, nervous, and frightened. In a paper which I recently read before the Kidderminster Medical Society I drew attention to fright as a not unimportant element in producing a fatal termination, and I insisted upon the importance of re-assuring and obtaining the confidence of the patient at the outset. May I now add that the factor of fright on the part of the administrator is a two-fold danger, because in addition to rendering him inefficient it must react upon his patient?

I notice in your excellent article[1] that you attribute this lack of knowledge to a certain extent to the fact that the examining bodies do not demand any special training in this important subject. Your estimate is no doubt correct and the time has now arrived when the General Medical Council ought to take cognisance of the matter and insist upon a different state of affairs. To-day, almost every practitioner is called upon to give anæsthetics on frequent occasions, and his want of knowledge is not only a detriment to himself but extremely irritating to the surgeons employed and a source of much discomfort and grave danger to the patient As a former anæsthetist at one of the largest London hospitals I have no hesitation in saying that there is ample material to give a thorough practical training to every individual student Take the number of a year's students at St Bartholomew's at 150, and the number of anæsthetics administered at 5000 it would certainly be a very easy matter for each student to administer 10 anæsthetics (I should prefer 20) My proposition is that the General Medical Council should insist that every practitioner should before receiving his diploma produce evidence that he has administered anæsthetics at least 20 times, including ether gas, and chloroform, under proper supervision There is a somewhat similar regulation with regard to confinements so why omit the anæsthetics? There can be no question of increasing the burdens of the student If he wishes to undertake the responsibility of administering anæsthetics surely he cannot complain if he is compelled to prove the possession of the necessary ability to do so I hope, Sirs, the General Medical Council will give their early attention to the matter

---

[1] THE LANCET, Oct. 20th, 1900, p 1164.

1215.

I am, Sirs, yours faithfully,
J LIONEL STRETTON
Senior Surgeon Kidderminster Infirmary and Children's Hospital formerly Assistant Anæsthetist St Bartholomew's Hospital.

THE ASSOCIATION OF PHYSICIANS AND SURGEONS (SOCIETY OF APOTHECARIES)

To the Editors of THE LANCET

SIRS —In answer to the further resolution of the Court of Assistants of the Society of Apothecaries the Association of Physicians and Surgeons (Society of Apothecaries) have replied thanking the Society for the authorisation to their Licentiates of adding to their titles of "L S A Lond" the words, "Physician and Surgeon and the Association hope that in the near future a further alteration will be made in a still rather unsatisfactory title Licentiates may now, on the authority of the resolution of Oct 8th, 1900, style themselves "Licentiate Physician of the Society of Apothecaries and Licentiate Surgeon of the Society of Apothecaries, London" ("L P S A and L S S A Lond")

I am, Sirs, yours faithfully,
GERALD DALTON,
Honorary Secretary of the Association of Physicians and Surgeons (Society of Apothecaries)
453 Strand W C Nov 12th 1900

HERNIA "SPECIALISTS"

To the Editors of THE LANCET

SIRS —I shall be obliged if any of your readers can furnish me with details of cases recently treated by Mr S J Sherman hernia specialist I think it likely that he attended patients in Cardiff about June of this year, and in Preston about the beginning of September All particulars which will assist in judging of the success or failure of Mr Sherman's treatment will be valued

I am, Sirs yours faithfully,
HUGH WOODS
Westbury Hornsey lane London, N., Nov 12th, 1900

PUBLIC VACCINATORS —At a meeting of the Council of the Association of Public Vaccinators held on Nov 9th it was decided to take immediate steps to press in the new Government the claims of public vaccinators to be considered as officers and to be eligible for superannuation and if necessary to proceed by the introduction of a private Bill in the ensuing Parliament As considerable expense will probably attend such an undertaking it was decided to make a special appeal to members of the association and to public vaccinators generally, so as to guarantee that the matter should not suffer for lack of funds A letter was read from the National Poor Law Officers' Association promising its help in any such enterprise

THE UNIVERSAL EXHIBITION OF PARIS

(FROM OUR SPECIAL CORRESPONDENT)

CONCLUDING NOTICE

CLOSURE AND SUCCESS OF THE EXHIBITION

AFTER the final illuminations unprecedented in brilliancy, expanse, and grandeur, the great Universal Exhibition of 1900 has closed its doors The best of things must end and this has certainly been the best and the most successful of Exhibitions Where in the world's history has it ever been recorded that more than 600,000 persons came in the course of a day to contemplate an Exhibition, however large and attractive? There has been some talk of failure, originating among those who, for political reasons, were anxious to damage the Government actually in office, and there have been failures, but not of the Exhibition The public, more especially the French public, has shown its good sense and its good taste by not patronising extensively certain side shows, but these do not constitute the Exhibition On the other hand, such side shows as the History of Costume, the Palace of Light with its scientific exhibits, the Trans Siberian railway, the Mareorama with its life like illusion of a Mediterranean cruise, and other panoramic displays were worthy of the Exhibition and were widely admired and patronised Others of a lower order failed and deserved to fail But these small side issues are inseparable from great exhibitions, for money must be raised in some way or another It is true that the Exhibition bonds bearing 65 000 000 admission tickets were readily sold for as many francs, but this, even when supplemented by subventions from the State and from the Paris municipality, did not suffice for such a vast undertaking Therefore, concessions were sold to various speculators Similar concessions were granted too cheaply for the Exhibition of 1889, and it is said that in the present case the charges made were too high In any case there has been over speculation, but the Exhibition cannot be held responsible for the miscalculations of individuals who wanted to run restaurants, side shows or stalls for the sale of trinkets Such establishments do not constitute an Exhibition they are rather the parasites that hang on to a great national enterprise Nor is it the fault of the management of the Exhibition if the restaurant keepers made such exorbitant charges and gave such poor food that a great number of visitors preferred to bring sandwiches with them or to take their meals at restaurants outside But those wiser caterers, such as the owners of the Swiss Châlet near the Eiffel Tower, who gave simple wholesome food and plenty of it at moderate charges must have made large fortunes, for the crowds of customers that patronised their establishments must have exceeded the wildest hopes that it was possible to entertain So that it may be said that where success was merited it was achieved and if some of the side shows failed this in a measure, may be attributed to the fact that there was so much to be seen in what constituted the Exhibition proper that but little time remained to visit anything else

Then, after all in judging an Exhibition it is first of all necessary to consider what is its main purpose Evidently this consists of gathering from all parts of the world exhibits that will illustrate the progress achieved in the domains of science art, and industry to which in this Exhibition have been added philanthropy and sociology Now under all these headings there have never been before so many and such remarkable exhibits The Palace of Social Economy and of the Congresses was a new and a remarkable feature Here on the ground floor was shown what the leading nations of the world have done to raise the poorer sections of the community by organising self help institutions, while on the upper floor vast assembly rooms were at the disposal of the 127 official International Congresses that were held Thus was stimulated a righteous rivalry and emulation in the performing of good works These endeavours cannot be ignored and will not be forgotten, they all contribute to the grateful memory that will long outlive the ephemeral life of the Exhibition itself In the course of a few months weighty volumes will be distributed throughout the world recording what was said and done at these congresses The report of the International Medical Congress will constitute a small residence, Banbridge, co. Down, on Nov. 6th, from exhaustion following carbuncle, after a short illness of two weeks. Born in Banbridge 65 years ago, his early education was obtained at the well-known school of Mr. Andrew Mullan. He afterwards studied at Queen's College, Belfast, where he was a hard-working student and obtained several prizes. In 1857 he became a Licentiate of the Royal College of Surgeons of Edinburgh, and in 1861 he graduated M.D. of the old Queen's University. Starting practice in his native town, Banbridge, his success was rapid, and in 1872 he was appointed medical officer of the Banbridge Union Infirmary and Fever Hospital. He was also a certifying factory surgeon and a justice of the peace for County Down. A man of sound professional knowledge, Dr. Hawthorne enjoyed the complete confidence of his patients. Taking an active part in the affairs of his native town and being a man of shrewd business habits his death is greatly deplored. He was buried on Nov. 9th, his funeral being attended by a large number of personal friends and former patients.

JOHN QUILLER COUCH, M R C S., L M. ENG., L S A. LOND,

CONSULTING SURGEON, PENZANCE INFIRMARY.

MR. J. QUILLER COUCH died at his residence, Chapel-street, Penzance, on Nov. 6th, in his seventieth year. Mr Couch, who belonged to an old Cornish family, was the son of the late Mr. Jonathan Couch, M R C.S, of Polperro. He received his medical education at Guy's Hospital and qualified M.R C.S., L M. Eng., and L.S A. in 1862. Mr. Couch had practised for many years in Penzance, having succeeded to the practice of his brother, Mr. R. Q. Couch The deceased held several appointments, being medical officer of health for the Madron and Ludgvan Urban Districts, medical officer and public vaccinator for the No. 5 District, Penzance Union, and surgeon to the Great Western Railway Company. He was also consulting surgeon to the Penzance Public Infirmary and Dispensary. Mr. Couch will be much missed in Penzance, where he was very popular. He had been in failing health for some time past, although he continued his professional duties up to the last month.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The The deaths of the following eminent foreign medical men are announced:—Dr. W. Browning, Professor of Anatomy, Long Island Hospital, Brooklyn, U.S.A.—Dr. Teijeiro, Professor of Clinical Surgery in the University of Santiago, Spain.—Dr G. Bulau of Hamburg.—Dr. Turnbull of Philadelphia, a voluminous author of books and papers on Diseases of the Eye.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a stated meeting of the College held on Nov. 9th the following successful candidates were admitted to their respective Licences:—

Licentiate in Medicine.—E J. M. Watson, M D.
Licentiates in Midwifery.—Miss Agnes Benjamin, L R.C.P. & S. Edin, and Miss Honorine Forbes, L.R.C P. & S. Edin

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Julius Lazarus of the Jewish Hospital has been granted the title of Professor.—*Bonn:* Dr Grouven has been recognised as *privat-docent* of Dermatology.—*Breslau:* Dr Thilenius of Strasburg has been appointed Extraordinary Professor of Anatomy. He has been a great traveller, having visited North America, Australia, and the Polynesian Islands in search of scientific information.—*Chicago (Rush Medical College):* Dr. Edwin Klebs, Professor of Pathological Anatomy, has resigned, and is returning to Europe.—*Christiania:* Dr. F. G. Herbitz has been appointed Professor of Pathological Anatomy.—*Gratz:* Dr Otto Barnik has been appointed *docent* of Otology.—*Kiel:* Dr Deetjen has been recognised as *privat-docent* of Physiology.

DR R T. MEADOWS has been elected an alderman by the Saltash Town Council.

APOTHECARIES' HALL OF IRELAND.—The following candidates have passed (October, 1900) the final examinations in medicine, surgery, and midwifery: D'Arcy Irvine Hamilton, John Thompson, and Stafford Adye Curran.

UNIVERSITY COLLEGE OF WALES.—The annual meeting of the University College of Wales was held at Aberystwyth on Oct. 26th. The annual report was favourable. The Bishop of Hereford delivered the inaugural address.

SUPERANNUATION ALLOWANCE.—Mr. Richard Ellery, L.R.C.P. Edin., M.R.C S. Eng., who has for 31 years been district medical officer of the Plympton (Devon) Board of Guardians, has been granted a superannuation allowance of £50 per annum.

BRISTOL MEDICAL SCHOOL.—The annual dinner of the Bristol Medical School will be held at the Royal Hotel, Clifton, on Nov. 22nd. Dr. Shingleton Smith will preside and Sir William Broadbent, Bart., will be the guest of the evening.

SALARIES OF MEDICAL OFFICERS OF HEALTH.—At the meeting of the Axminster Rural District Council held on Nov. 8th a letter was read from the Local Government Board refusing to sanction the reappointment of the medical officer of health. In a former communication the Board had intimated that they would take this step unless a larger salary was granted.

DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students will be held on Saturday, Nov. 24th, at the Whitehall Rooms, Hôtel Métropole, under the presidency of Mr. F. A. Bevan, a trustee and vice-president of the hospital. Gentlemen either now or formerly connected with the hospital or medical school who may through inadvertence not have received special notice and who desire to be present are requested to communicate with the Dean at the Dental Hospital, 40, Leicester-square, London.

LITERARY INTELLIGENCE.—Mr. George Henry Makins, F.R.C.S Eng., surgeon to St Thomas's Hospital and late consulting surgeon to the South African Field Force, has in active preparation a work which he entitles "Surgical Experiences in South Africa, 1899–1900: being mainly a Clinical Study of the Effects of Injuries produced by Bullets of Small Calibre." The volume will be published by Messrs. Smith, Elder, and Co.—The increasing interest taken in the study of astronomy has induced the proprietors of *Knowledge* to issue an annual for students and workers in that science specially devoted to their requirements. It is entitled "Knowledge Diary and Scientific Handbook, 1901," and will contain amongst other things useful tables, original articles, a calendar of scientific events, and a blank diary portion. The price is 3*s.* net, and the diary is published at 326, High Holborn, London, W.C.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The annual breakfast meeting given by the British Medical Temperance Association to medical students was held at the Cannon-street Hotel, London, on Nov. 9th. There was a large attendance, including students from the London Hospital, Guy's Hospital, St. Thomas's Hospital, King's College Hospital, St Mary's Hospital, Middlesex Hospital, and the London School of Medicine for Women. Professor Sims Woodhead presided and the meeting was addressed by Mr. A. Pearce Gould, Mrs. Scharlieb, Dr. J. Dixon, Mr. W. McAdam Eccles, and Dr. J. J. Ridge.—Mr. Pearce Gould said that they were not asked to join a waning but a growing cause. The alteration in the medical and surgical use of alcohol in the last 30 years had been immense; so also had been the estimate formed by business men of the value of total abstainers, whose lives were formerly considered uninsurable at ordinary rates, whereas now every life insurance office was only too glad to get them. Total abstinence would enable them to make the best use of their powers and was helpful physically, mentally, and morally. Alcohol never gave self-control or added to a man's power of work. The responsibility was great in view of the terrible havoc caused by drink, not only by the coarser forms of drunkenness but in its more insidious forms, and he hoped that they would not become hard and callous to all this. He could not help those who were given to drink so well if he were not an abstainer himself, and there were many needing help whose moral faculties had been weakened. He would also remind them that though there was a large pathology of alcohol there was absolutely none of total abstinence.—Mrs. Scharlieb also urged them to join the association. Her experience in India was that the abstaining natives were most excellent patients, and in severe illness such as enteric fever and in operation cases did well in a way she had never seen others do. She rarely used alcohol even in the most severe operations. There had, no doubt, been great improvement in some of the drinking customs, but if England used the millions spent on alcohol in other ways it would be a blessing to the world. She believed that if they abstained they would be stronger in body, soul, and spirit.—Votes of thanks were passed to the speakers and to Professor Sims Woodhead. 19 students afterwards joined the association.

Births, Marriages, and Deaths.

BIRTHS.

Ensor.—On Nov. 2nd, at Tisbury House, Tisbury, Salisbury, the wife of Cecil Arthur Ensor, M.R.C.S., L.R.C.P.—a daughter, prematurely.

Griffith.—On Nov. 6th, at Tanyronen, Portmadoc, N. Wales, the wife of Harry R. Griffith, M.D., of a son.

MARRIAGES.

Scott—Peel.—On Nov. 8th, at the Brompton Oratory, William John Scott, L.K.Q.C.P.I., of Hurstpierpoint, Sussex, to Julia Rose Steers Peel, of Laregon, Gloucestershire.

Winter—Witherby.—On Nov. 7th, at All Saints' Church, Chilvers Coton, Nuneaton, John Newnham Winter, M.R.C.S. of Montpellier-road, Brighton, to Amy Florence, eldest daughter of Josiah Witherby, of King's-avenue, Ealing, Middlesex.

DEATHS.

Blackwell.—On the 8th Nov., at his residence, "Inverary," Westcliff-on-Sea, Frederick William Blackwell, L.R.C.P.E., L.R.C.S.E., aged 49 years.

Cordwent.—On Nov. 12th, at Milverton, Somerset, George Cordwent, M.D. St. And., F.R.C.S. Eng., aged 85 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"A MEMORIAL TO THE GENERAL MEDICAL COUNCIL FROM THE MIDDLESBROUGH AND DISTRICT MEDICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of Nov. 10th (p. 1395) a letter from the honorary secretary of the Middlesbrough and District Medical Society in which he calls attention to a test case which is being presented to the General Medical Council on the question of the association of medical men with medical aid societies which canvass. The result of this memorial, as you remark, will be watched with interest by the medical profession. It is important in view of the extent to which touting in connexion with clubs and insurance societies prevails to have some authoritative expression of opinion from the General Medical Council and to know whether their resolution of last June is merely the record of a "pious opinion" or whether their declaration of conduct being unprofessional is likely to be followed by penal consequences where it is proved to exist. In the town in which I practise this system of canvassing is in full operation. One medical firm has a large private family club, the agents for which are the canvassers for one of the largest industrial insurance companies. This insurance company, I believe, has no knowledge of, or interest in, this part of the work of its agents as it does not supply medical aid and I daresay the medical firm in question would repudiate the idea that these agents canvass for them, but the fact remains that these agents, who canvass the whole town in the interests of the insurance company, are also the agents for the private club of this firm, and it is quite certain that they canvass and do their best for both their employers Their usual plan is to call upon a family to get them to insure and then to ask them if they will also join Dr. So-and-So's sick club at 1½d. per week. As they get a large percentage *on the receipts it is manifestly to their advantage to get all the* patients into their net which is possible. Thus it happens that the patients of other medical men are constantly being solicited and many complaints are heard. What is the remedy for this abuse? The mere statement that it is unprofessional by the General Medical Council can have no effect if it be merely a "pious opinion." If it be pronounced "infamous conduct in a professional respect" it will without doubt have the effect of remedying a great abuse and of raising the standard of medical practice generally. I call attention to the practice of employing collectors to canvass for members for private family clubs because it does not appear to me to be completely covered by the resolution of the General Medical Council of last June. It might be urged that a medical man has a right to have a private club and to employ a collector to go round once a week to collect the fees and that this does not constitute touting But where an agent is paid by results I do not see how canvassing can be avoided At any rate, the system is so liable to abuse that I am of opinion it ought to be dealt with. In the particular instance which I have mentioned the agency is more complete than that which any medical man himself could organise, as the town is divided into districts by the insurance company and the canvassing is necessarily most exhaustive The firm in question, however, might seek to evade the condemnatory resolution of the General Medical Council by saying that these insurance agents were merely their private collectors and that they had no knowledge of their canvassing I feel very strongly, *therefore, that if this question comes up for consideration by the* General Medical Council and any action is taken it should forbid the employment of collectors for private family clubs, and above all, the employment of the agents of an insurance company or of any other organisation for this purpose.—I am, Sirs, yours faithfully,

Nov. 12th, 1900. A SUFFERING PRACTITIONER.

THE CASE OF MR. JOSEPH HENDERSON MARTIN.

To the Editors of THE LANCET.

SIRS,—The following subscriptions have been received by Dr. W. M Renton and myself in response to the appeal for help for the family of Mr. J. H. Martin. M.R.C.S Eng., L.S.A., which appeared in THE LANCET of Nov. 10th. *I am, Sirs, yours faithfully,*

Chester-le-Street, Nov. 14th, 1900 H. LYON SMITH.

VARIX

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers oblige me by giving me the names of any recent book or writing on varix, especially varicose veins of the legs? I am, Sirs, yours faithfully,

Nov. 11th, 1900. LEX.

AN ETHICAL POINT.

To the Editors of THE LANCET.

SIRS,—I should be pleased if you could give me your opinion on the following case. Dr. X died in September, 1897, leaving a widow and no successor to the practice. Since his death up to the present time the widow has engaged six medical men, each of whom has worked the practice for various periods, the widow receiving a certain percentage of the receipts. During her husband's lifetime she was in the habit of occasionally vaccinating children, dispensing and dressing wounds in the surgery, and has done this more or less up to the present time. Dr. A now comes forward and offers to buy the practice, including the drugs, fixtures, &c., on condition that she absolutely refrains from doing any medical work whatever, her only position being that of housekeeper. All this is incorporated in a legal agreement. 1. Could Dr. A's conduct *be construed so as to constitute covering? 2. Is Dr. A behaving* professionally by keeping the widow as housekeeper?

I am, Sirs, yours faithfully,

Nov. 13th, 1900. QUANTUM SUFFICIT.

*** Dr. A places himself in a position which is liable to misconstruction, but if he does not act unprofessionally he has nothing to fear.—ED. L.

THE LATE DR. PATRICK QUINLIVAN.

WE gladly publish the following appeal which is being circulated on behalf of the family of the late Dr. Patrick Quinlivan of 254, Bethnal-green-road The committee, according to the printed appeal, consists of the following gentlemen: "H. Macnaughton Jones, M.D., F.R.C.S.I.,; Frederick J. Smith, M.D., F.R.C.P.; P. J. Freyer, M.D., M.Ch.; Dr. Rogers, Dr. O'Dwyer, Dr. Daly, Dr. Ambrose, Dr. O'Malley, Dr. Cahill, Dr. Sheehan, Mr. Winter. Honorary treasurer, Dr. R. Ambrose, M.P., The Mount, Whitechapel road, E." The appeal runs as follows.—

> DEAR SIR,—We beg to bring before your notice this appeal as being one well deserving of your sympathy. Dr. Quinlivan died at the age of 36 years—unexpectedly—from an attack of acute pneumonia, leaving a widow and a family of seven children—whose ages range from nine months to 13 years—unprovided for. The committee confidently appeal to you to aid them in purchasing a small business by which the widow may support herself and her family. Yours faithfully,
>
> 150, Bethnal-green-road, N.E R. MOYNAHAN, Hon. Sec.

Subscriptions to the amount of £41 16s. have already been received we shall publish the names of subscribers next week.

TOMATOES AND CANCER.

To the Editors of THE LANCET.

SIRS,—I have latterly been often asked by patients if I believed in the theory that tomatoes as a food were a fruitful source of cancer. They assert that eminent men have declared them to be so. I have never until recently heard of the theory. Would you be good enough to enlighten me? I am, Sirs, yours faithfully,

Nov. 13th, 1900. H. W.

*** There is no truth whatsoever in the idea.—ED. L.

MANURE AND MUNICIPALITIES.

WE have received a card bearing the following legend from a Brighton correspondent.—

Friday, 9th November, 1900.

The Poor of Aldrington respectfully invite

THE MAYOR AND CORPORATION OF HOVE

TO VISIT TO-DAY:

The overflowing Cesspool near the Portland-road Board School.

The Dust Heap opposite.

And the Outfall Sewer at low tide.

They will then understand why the death-rate of children in Aldrington is nearly three times that of Hove.

And why poor people think their sanitation should be attended to before rich people's circular drives.

We shall be interested to know whether his worship accepted the invitation. Possibly he and the corporation are of the same opinion as was the Corporation of London in the days when *Mr. Punch* drew the members of that august body sitting in Smithfield, exclaiming: "How delicious the drains smell this morning," while their children played with little pails and spades among the dung.

PRURITUS ANI.

To the Editors of THE LANCET.

SIRS,—"Perplexed's" patient would find great benefit and relief in pruritus ani and scroti, as well as in tinea sycosis, by the free rubbing in of Calvert's Carbolic Soft Soap every night, which should be allowed to remain on an hour and then washed off.

I am, Sirs, yours faithfully,

GEO. ARNISON, M.R.C.S. Eng.

Allendale Town, Northumberland, Nov. 10th, 1900.

"ADHESIVE PLASTER FOR PUNCTURED TYRES"

To the Editors of THE LANCET.

SIRS,—In reply to "Cyclist" in THE LANCET of Oct. 27th, p. 1249, I may say that I have tried the various "rubber adhesive plasters" in the market for repairing punctures, but they all proved unsatisfactory when applied to the air tube. Such plasters, however, are invaluable for temporary repairs of the tyre cover and can be applied inside or a strip long enough to be gripped by the rim on both sides may be applied externally over a gash or unusually large hole.

I am, Sirs, yours faithfully,

Oct. 27th, 1900. A. S. G.

ORCHITIC EXTRACT.

To the Editors of THE LANCET.

SIRS,—I should be glad of any information on the following points. 1. Are there any dangers to be apprehended in the administration of orchitic substance (didymin) by mouth and rectum? 2. Can you advise me of any literature on the subject of the therapeutics of the administration of orchitic substance?

I am, Sirs, yours faithfully,

Nov. 9th, 1900. PROSTATE.

*** 1. No dangerous symptoms have ever been described as resulting from the administration of this substance. 2. We know of no summary of the therapeutics of orchitic substance, but the following papers may be referred to: THE LANCET, vol. ii., 1889, p. 105; THE LANCET, vol. i., 1893, p. 1357; *London Medical Record*, 1890, p. 209; *London Medical Record*, 1891, p. 165; *British Medical Journal*, vol. i., 1893, p. 1212; THE LANCET, vol. i., 1891, p. 1291; *Medical Press and Circular*, vol. ii., 1892, p. 455.—ED. L.

"TOBACCO HEART."

To the Editors of THE LANCET.

SIRS,—Will you kindly direct me through the medium of your columns to any existing literature on the subject of "Tobacco Heart"?

I am, Sirs, yours faithfully,

Nov. 13th, 1900. B. B. G.

*** Our correspondent will find numerous references in Neale's Digest. —ED. L.

SMOKING IN EPILEPSY.

To the Editors of THE LANCET.

SIRS,—Can you tell me whether moderate smoking is supposed to be injurious in epilepsy as I cannot find it referred to in the text-books I have at my command? I am, Sirs, yours faithfully,

Nov. 13th, 1900. EPILEPSY.

*** We do not remember having heard this question raised before. Moderate smoking is a term difficult to define; it is, however, possible that the amount of tobacco which would do no injury to a person in perfect health might be inadvisable for one in the unstable nervous condition of an epileptic.—ED. L.

NERVE STRETCHING.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me where I can find details of the technique of stretching the sciatic nerve by extension and flexion of the limb? I thought I had seen an article upon the subject in a recent number of THE LANCET but have been unable to find it. Thanking you in anticipation, I am, Sirs, yours faithfully,

Nov. 10th, 1900. SPES.

*** The "bloodless" method of stretching the sciatic nerve is performed as follows: The patient lies on his back and the surgeon extends the knee joint and then flexes the hip forcibly. An anæsthetic is only needed if much force is used.—ED. L.

HOMES FOR EPILEPTICS.

To the Editors of THE LANCET.

SIRS,—I should be obliged if you or any of your readers could inform me of an institution that would take charge of a girl suffering from epilepsy. The parents could only afford to pay about 5s. or 6s. a week.

I am, Sirs, yours faithfully,

Nov. 13th, 1900. W. H. C.

*** Our correspondent might apply to the Meath Home of Comfort, Westbrook, Godalming, Surrey. There is also the epileptic colony at Chalfont St. Peter, the London offices of which are at 12, Buckingham-street, Strand, W.C.—ED. L.

THE PROPERTY IN A PRESCRIPTION.

To the Editors of THE LANCET.

SIRS,—Will you kindly let me know through the columns of THE LANCET who is the *legal* owner of medical prescriptions given to a patient on payment of a fee for consultation? Can you refer me to any recorded legal decision on the question?

I am, Sirs, yours faithfully,

Nov. 9th, 1900. L. K.

*** "L. K." is not sufficiently explicit for us to be able to give him an altogether satisfactory answer. The "legal owner of medical prescriptions given to a patient on payment of a fee for consultation" is presumably the patient so far as ownership of the piece of paper containing the prescription is concerned. Ownership of a piece of paper does not, however, necessarily imply an unqualified right in such owner to deal as he pleases with its written contents, as, for example, to multiply copies of them. We are not, however, aware of any decision limiting the rights of ownership in the contents of a written document and dealing directly with a prescription.—ED. L.

BOOKS ON SURGERY.

N. A. B.—The following works may be referred to:—"Manual of Surgery for Students," by W. Rose, F.R.C.S. Eng., and Albert Carless, F.R.C.S. Eng., pp. 1160 and 400 illustrations, price 21s. London: Baillière, Tindall, and Cox. "Student's Handbook on Surgical Operations," by F. Treves, F.R.C.S. Eng., 94 illustrations, price 7s. 6d. London: Cassell and Co. "The Operations of Surgery," by W. H. A. Jacobson, F.R.C.S. Eng., third edition, price 34s. London: J. and A. Churchill. "Surgical Handicraft, a Manual of Surgical Manipulations and Minor Surgery," by Walter Pye, F.R.C.S. Eng.; revised and edited by T. H. R. Crowle, F.R.C.S. Eng., third edition, 1891, with 235 engravings, price 10s. 6d. Bristol: John Wright and Co. "A Manual of Surgical Treatment," by W. Watson Cheyne, F.R.C.S. Eng., and F. F. Burghard, F.R.C.S. Eng., to be completed in six parts. London: Longmans, Green, and Co. Only the first three volumes have yet been published.

THE EXAMINATION FOR F.F.P.S. GLASGOW

G.P. would be glad to hear from someone who has recently been a competitor particulars regarding the examination for F.F.P.S. Glasgow—(1) if the examination is very stiff; (2) if any special text-books are recommended; and (3) as to the chance of a man in busy practice, who has not a great deal of time for reading and who is not in touch with any hospital, obtaining the qualification.

WE have had this week to vary the noms-de-plume of several of our correspondents who have used the same signature to their communications.

◆

Enquirer.—There is no difference in value between the qualifications, in that each combination entitles a man to be placed on the Register, showing that he has attained to the standard required by the General Council of Medical Education. A Licentiate of the Royal College of Surgeons of Edinburgh is not correct in placing the prefix "Dr." before his name.

Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.)

TUESDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (21st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (22nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (24th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (20th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—Dr. S. H. Habershon and Dr. F. S. Hichens: A Case of Pseudo-Actinomycosis.—Mr. W. G. Spencer: (1) Fibroma of Tongue; (2) Spheroidal-celled Carcinoma commencing in Supernumerary Nipples.—Dr. W. Hunter: A Case of Acute Yellow Atrophy. Card Specimen: Mr. T. W. P. Lawrence: Hour-glass Contraction of Stomach.

CHELSEA CLINICAL SOCIETY (Holy Trinity Parish Hall, Pavilion-road, Sloane-square, S.W.).—8.30 P.M. Paper:—Mr. N. Smith: The Conservative Treatment of Tubercular Disease of Joints (with demonstration).

WEDNESDAY (21st).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—7.30 P.M. *Exhibition of Slides illustrating the Structure of Shells.*

SOCIETY OF ARTS.—8 P.M. Ordinary Meeting. Opening Address:—Sir John Evans.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11, Chandos-street, Cavendish-square, W.).—4 P.M. Papers:—Sir Dyce Duckworth: On Mental Disorders dependent on Toxæmia.—*Dr. G. H. Savage*: Travel, its Use and Abuse in the Treatment of Mental Diseases.—Dr. L. Jones: The Application of Electricity in certain forms of Mental Disease (illustrated with instruments and electrical appliances).

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Gt. George-street, Westminster, S.W.).—7.30 P.M. Ordinary Meeting. Papers:—Mr. R. H. Curtis: An Improved Mounting *for the Lens* and Bowl of the Campbell-Stokes Sunshine Recorder.—Mr. W. H. Dines: Weekly Death-rate and Temperature Curves, 1890-1899.—Mr. H. Mellish: Seasonal Rainfall of the British Islands.

FRIDAY (23rd).—CLINICAL SOCIETY OF LONDON (20, *Hanover-square*, W.).—8.30 P.M. Papers:—Dr. S. Phillips: A Case of Thrombosis of the Inferior Vena Cava and of the Iliac and Femoral Veins of Acute Onset and Fatal Termination, with symptoms resembling those of Perforated Gastric Ulcer.—Mr. C. Williams: *A Case of late* Syphilitic Pyrexia.—Mr. Bland Sutton: On a Case in which Splenectomy was performed for a Wandering Spleen.—Dr. W. P. Herringham: A Case of Nephritis without Albuminuria; Death in Six Weeks; no Scarlet Fever; Necropsy.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, *Chenies-street*, W.C.).—4 P.M. Dr. J. F. Payne: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: Surface Anatomy.

TUESDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. S. J. Sharkey: Consultation. (Medical.)

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—5 P.M. Clinical Lecture:—Dr. P. S. Abraham: Psoriasis.

WEDNESDAY (21st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Clinical Lecture:—Mr. J. Cantlie: Plague.

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—5 P.M. Dr. F. Potter: Selected Cases. (Post-graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Latham: Phthisis in Early Childhood.

THURSDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—3 P.M. Dr. H. Low: Class. Practical Application of Roentgen Rays. 4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Wallace: Pathological Demonstration.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL (Gray's Inn-road, W.C.).—8 P.M. Clinical Evening. Dr. P. Jakins: Demonstration of Cases of Diseases of the Throat and Nose.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. C. B. Keetley: General Treatment of Wounds and of Compound Fractures.

FRIDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. H. Spicer: Consultation. (Eye.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *Swindon Times, Northampton Herald, Dewsbury Reporter, Gloucester Journal, Derbyshire Times, Newcastle Journal, Lynn Advertiser, Southern Times, Bradford Observer, Indian Daily Telegraph (Lucknow), Times of India, Pioneer Mail, Alliance News, Builder, Architect, Sheffield Daily Telegraph, Staffordshire Advertiser, Dundee Advertiser, Scotsman, Citizen, Manchester Guardian, Glasgow Herald, Oldbury Weekly News, Lancaster Post, Glasgow Herald, Leicester Mercury, Birmingham Gazette, Rushden Argus, Oxford Journal, Hyde Reporter, Liverpool Daily Post, Evesham News, Kendal Times, Wolverhampton News, Bristol Mercury, Cardiff Times, Shields News, Leeds Mercury, Halifax Courier, Yorkshire Post, Thames Valley Times, Mining Journal, Westminster Gazette, Reading Mercury, City Press, Hertfordshire Mercury, Sanitary Record, Church Weekly, Croydon Post, Vectis, South London Mail, Chemist and Druggist, Bristol Times and Mirror, Surrey Advertiser, Local Government Journal, Lincolnshire Echo, Lincolnshire Chronicle, Halstead Gazette, South Shields Free Press, Express, Sun, Bath Argus, Daily Mail, Reynolds's Newspaper, Free Lance, Leighton Buzzard Reporter, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Mr. F. Aston, Lond.; Miss A.; Messrs. Arnold and Sons, Lond.; Messrs. Allen and Hanburys, Lond.; Association of Physicians and Surgeons, Lond., Hon. Secretary of. Alpha, Sheffield; Dr. R. Ambrose, Lond.

B.—Dr. Biga, Barcelona; Messrs. Burgoyne, Burbidges and Co., Lond.; Birkenhead and Wirral Children's Hospital, Secretary of; Brixton Dispensary, Secretary of; British Somatose Co., Lond.; Bathwick Nursing Home, Bath, Proprietress of; Bedford College Lond., Hon. Secretary of; Messrs. Burroughs, Wellcome and Co., Lond.; Barnsley, Mayor of.

C.—Mr. F. G. H. Cooke, Lond.; Dr. W. T. Cocking, Sheffield; Mr. E. M. Corner, Lond.; Cortland Wagon Co., Lond.; Mr. A. R. Clarke, Brighton; Croydon General Hospital, Secretary of; Mr. Mayo Collier, Lond.; Church of England Temperance Society, Secretary of; Mr. G. Chalmers, Lond.; *China Medical Missionary Journal*, Chefoo, Editor of, Children's Hospital, Nottingham, Secretary of, Mr. J. Cropper, Chepstow; Mr. J. W. Collett, Hull; Camberwell, Lond.

D.—Mr. J. C. Dewar, Edinburgh; Dental Hospital, Lond., Dean of; Darton Gibbs Co. (The), Oldbury; Dewsbury, Mayor of; Derbyshire Royal Infirmary, Secretary of.

E.—Enquirer, Wyke Regis; Messrs. J. Elliott and Co., Lond.; Mr. J. Eckhardt, Honolulu, Hawaiian Islands.

F.—Mr. P. J. Freyer, Lond.; Forfarshire Medical Association, Hon. Secretary of.

G.—Dr. T. Law Gaskin, Barbados; Mr. E. Grillon, Lond.; G.; Mr. J. C. Goodman, Barnsley; Dr. T. W. Griffith, Leeds; Dr. J. E. Gemmell, Liverpool; Mr. E. Goody, Llandudno; G. P., Lond.; G. P., Doncaster; Messrs. A. E. Gibson and Co., Lond.; Dr. F. W. Grant, Elgin.

H.—Mr. H. J. Hutchens, Brisbane; Messrs. Hastings Bros., Lond.; Mrs. Hoddinott, Evesham; Hull Royal Infirmary, Secretary of; Dr. T. W. Hime, Bradford; Dr. Fletcher Horne, Barnsley; Mr. R. Hughes, Morriston; Dr. G. A. Heron, Lond.; Mr. E. A. Haynes, Perth, Australia; Dr. J. Haddon, Denholm.

I.—Messrs. Ingram and Royle, Lond.; International Sleeping Car Co., Secretary of; Messrs. Innes, Smith, and Co., Birmingham.

J.—Mr. Mark Judge, Lond.; Mr. H. O. Jones, Amlwch; J. K. F.

K.—Dr. J. H. Kellogg, Battle Creek, U.S.A.; Messrs. Kegan, Paul and Co., Lond.; Kidderminster Infirmary, Secretary of; Kingston-on-Thames Union, Clerk to.

L.—Mr. H. Littlewood, Leeds; Mr. J. L. Leckie, Pontypridd; Mr. T. Laffan, Cashel; Leeds Infirmary, General Manager of; Lostwithiel, Mayor of; L. H.; Launceston, Mayor of; Mr. L. F. Layton, West Hartlepool

M.—Mr. R. de Martini, Lond.; Medical Society of Victoria, Melbourne, Hon. Treasurer of; Medico-Psychological Association, Secretary of; Messrs. Morris, Thomas, and Ellis, Birmingham; Mr. W. J. Messenger, Lond.; Messrs. C. Mitchell and Co., Lond. Mr. A. Maude, Westerham, Medical Graduates' College, Medical Superintendent of; Messrs. Macmillan and Co., Lond.; Messrs. J. F. Macfarlan and Co., Lond.; Mr. R. Morison, Newcastle-on-Tyne; Dr. T. J. Maclagan, Lond.; Maltine Manufacturing Co., Lond.

N.—Dr. J. E. Nevins, Liverpool; National Mutual Life Association of Australasia, Manager of.

P.—Mr. Y. J. Pentland, Edinburgh; Dr. A. Pewnitzky, Odessa, Russia; Dr. O. Paget, Freemantle, Australia; Prostate, Clevedon.

Q.—Quex Manufacturing Co., Manchester.

R.—Mr. G. Rees, Aberystwyth; Mr. J. Ritchie, Lond.; Royal Medical Society, Edinburgh, Secretary of; Ruthin, Mayor of; Dr. Forbes Ross, Lond.; Royal Devon and Exeter Hospital, Exeter, Secretary of; Ramsgate and St. Lawrence Dispensary, Secretary of; Royal Albert Hospital, Devonport, Secretary of; Royal Southern Hospital, Liverpool, Secretary of; Royal Institute of Public Health, Secretary of; Royal College of Physicians, Edinburgh, Secretary of; Mdlle. A. Révy, Lond.; Messrs. Reynolds and Branson, Leeds; R. J.; Mr. B. T. Read, Winchfield.

S.—Mr. P. Steadman, Lond.; Mr. G. A. Stevens, Swansea; Mr. S. Stephenson, Lond.; Mr. E. Saywell Nottingham, Messrs. Sharratt and Hughes, Manchester; Mr. C. F. Steele, Lond.; Messrs. Squire and Sons, Lond.; Springfield House, Bedford; Medical Superintendent of; Messrs. T. and H. Smith and Co., Lond.; St. Mary's Hospital Medical School, Secretary of; Mr. O. Smithson, Kettering; St. Giles, Camberwell, Vestry of; Messrs. Smith, Elder and Co., Lond.; Strenbo Co., Manchester; Messrs. G. Street and Co., Lond. Scholastic, Clerical, &c., Association, Lond.; Sanitary Assurance Association, Secretary of; Sanitary Institute, Registrar of; Professor Charles Stewart, Lond.; Mr. H. W. Spaight, Ramsgate; Sanitary Institute, Registrar of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

MENTAL DISORDERS DEPENDENT ON TOXÆMIA.

Delivered before the Medico Psychological Society on Nov 21st, 1900,

BY SIR DYCE DUCKWORTH, M D,
LL D EDIN, F R C P LOND,
TREASURER AND CENSOR, ROYAL COLLEGE OF PHYSICIANS OF LONDON
PHYSICIAN AND LECTURER ON MEDICINE, ST BARTHOLOMEW'S
HOSPITAL HONORARY PHYSICIAN TO H R H THE
PRINCE OF WALES

GENTLEMEN,—In addressing a body of experts in a special department of medicine such as now forms my auditory I might claim some indulgence for one who has to teach the whole subject of medicine. I will confess, however, that when I accepted with some diffidence the invitation of your honorary general secretary to undertake this duty I did so in order that I might venture to address you from the standpoint of general medicine, as one unconnected with any special department of it, and who regards your particular work as an important branch of our great art. The title of your association indicates that you acknowledge the fact that the science of psychology has a medical side. It is, of course, possible to be a psychologist without being a physician, and large achievements have accrued to the science at the hands of those who do not pretend to any gifts of healing. You avail yourselves of these, but many of you materially add to the general knowledge of psychology from your studies and observations as alienists. The pure, or non medical, psychologist is largely indebted to you for your researches. He may contribute to the study of mental evolution, while you lay bare pregnant facts relating to cerebral dissolution, for these, alas, you have daily experience of. In setting myself to the task of this address my thoughts naturally reverted to the days when I had the privilege of attending Professor Laycock's lectures on Medical Psychology at Edinburgh. These prelections were much in advance of their time and were the utterances of one of the shrewdest and most far thinking men of his day. We were perhaps too young to appreciate them fully, but they were eminently suggestive and afforded a splendid groundwork on which, at all events, some of his pupils have since reared solid and enduring structures. At that time this instruction was by some derided as unfit to form part of a medical curriculum, but such was not the view of those who considered that an academic training constituted something better than an ordinary curriculum. With these lectures were combined regular visits to various asylums for the insane, and so the training was thorough and practical. At that time the brain as an organ was only beginning to be studied otherwise than as a mass of nervous matter with sundry prominent and depressed portions whose names were difficult and sesquipedalian. Broca was at work, and Fritsch and Hitzig, followed by Laycock's pupil Ferrier, were soon in the field and opening out for us the vistas which we readily see to day in contemplating cerebral centres and functions. In this new aspect it is profoundly interesting to find that the prescience of Laycock had predetermined not a little of that which exact and laborious research came to reveal eventually in respect of function and localisation.

"You know better than I how much more has since been accomplished in these directions by our own countrymen, such as Schäfer, Horsley and Beevor, Risien Russell, Mott and others, to say nothing of the achievements of foreign investigators. The unknown and unexplored cerebral dark continent has now been mapped out and closely surveyed, what was, as it were, an untracked and undefined ocean is now sounded and charted and the bearings of many headlands have been duly taken. All is not yet done, however, albeit the work grows more complete, many investigators are still engaged upon it, and we can feel without doubt that among the wonders of the twentieth century the survey will be achieved and the minute anatomy and precise physiology of the whole nervous mass of the body made known. Let us try to imagine what Harvey, Hunter, Willis, Abercrombie, Bernard, and Connolly, with many others, would have thought of this in their day.

Regarded from the purely anatomical and physiological side of its nature we may venture to ask ourselves whether we be possibly over engrossed just now with the studies which thus relate to the material structure and function of the brain, and somewhat apt to forget or to neglect some of those higher and mysterious problems which attach to it as an organ of mind and the dwelling place of the immortal spirit of man. Doubtless such considerations more occupied the thoughts of our predecessors at a time when a minute study of the brain such as is possible to day was undreamed of. As a body we of the medical art have often been regarded as given over to materialism. I have always felt that such a stigma was unjust, and attributed it to the narrowness and self sufficiency of ecclesiastics who quailed before the manifestations of God's laws as exposed by science, and who could not bring themselves to accept anything that controverted their inflexible dogmatism. Such problems as I refer to are not merely for the contemplation of the theologian or the psychologist, for they must enlist the interest of every rational man, and certainly cannot be disregarded by the alienist who studies and ministers to, the distempered mind. To the thoughtful physician the human brain is not, as the heart or the liver or the kidney, an organ whose mechanism is merely appropriate for specific animal functions. It is, indeed, as marvellously adapted for its work as any of these, but that work is more varied more subtle, and more commanding than that of any other in the body. We do not now seek to localise in it the seat of the soul, as did our predecessors. We are content with the belief that in some inscrutable way the organ of mind and intellect is possessed by an unseen and intangible power, a divine essence, we will term it which, implanted in it from the first stirrings of life,[1] and having capacity for infinite development brings it into relation with the worlds unseen and only retires from its intimate tissue as the vital force ebbs out to assume a fresh and, as we hope, a better environment.

Respecting the relation of the material and spiritual in the human body,[2] the Church, as Canon Gore kindly informs me, has fortunately never made any dogmatic pronouncement. I say fortunately, for if it had made such a pronouncement in ancient or mediæval times with their false physiology they would certainly have made it wrong. On the other hand early Christian psychology, as in Tertullian, is very interesting because it insists on the unity of the human personality and protests against the subdivision of man into separate faculties—intellect, emotions, &c.—as if they were so many separate entities. I mean, it is interesting to see that Christianity intensified the sense of the unity of the human person—body, soul, and spirit. Tertullian asserts, against some Greek thinkers, that the "anima"—the vital principle or personality—is, while manifested in its faculties, none the less one. It thinks in feeling and feels in thinking. It is the same that wills or loves or is indignant or thinks—"Eadem quae perinde per corpus corporalia sentiat, quaemadmodum per animum incorporalia intelligat, salvo eo, ut etiam sentiat dum intelligit. Non essim et sentire intelligere est, et intelligere sentire est? ...... Quis mihi exhibebit sensum non intelligentem quod sentit, aut intellectum non sentientem quod intelligit?" (De Anima. Cap. VIII.) "Atque secundum officium operis sui variis nuncupatur nominibus: anima est, dum vivificat; dum contemplatur, spiritus est; dum sentit, sensus est; dum sapit, animus est; dum intelligit, mens est; dum consentit, voluntas est; dum discernit, ratio est; dum recordatur, memoria est. Non tamen hæc ita dividuntur in substantia sicut in nominibus; quia haec omnia una est anima." (Alcuin, "De Ratione Animae," 149.) This, one may say, is consistently the Christian view—that the person is one, with many faculties. In other words, the soul is πολλῶν ὀνομάτων μορφὴ μία.

---

[1] "Man became a living soul."—Gen. ii. 7.

"This is the instrument of God's masterpiece—the human soul. Over these nodes and fissures it floated, like the spirit of God over the face of the deep. Here as on a beautiful instrument the spirit touched the keys and thought, like music, came forth. And here were impressed indelibly ideas of the vast universe, without, of time, and eternity; yea, even of the Infinite and Transcendent—of God. Hushed in the silence of prayer here the soul brooded as a dove above its nest, and here in moments of temptation and repentance it argued, reasoned, prayed, implored the inferior powers that rebelled or recanted beneath. With what sublime majesty it ruled and swayed the subjects that owned its imperial dominion, and how it [illegible] heaven on the one hand for pity and earth on the other in power. And when the turbulent passions raged and stormed it soothed and quelled their rebellion, and then in recompense to itself [illegible] up towards the celestials and joined its emancipated sisters [illegible] the great white throne and drank in peace and the [illegible] of calm from the silence and worship of Heaven. Where is that soul now? Whither has it gone? Silent is the instrument but crumbling to inevitable decay. But where in the boundless [illegible] space is the deathless spirit that once ruled it in majesty [illegible] from [illegible] whose echoes roll through eternity? And I [illegible] science mapped and parcelled like a dead planet. Here is the 'island of Reil,' here the pons Varolii, here is the arbor vitæ, and there is the subarachnoid space, and here that wonderful contrivance of the great Designer that regulates the arterial supplies. [illegible] reverently and whisper 'Laudate!'"—"My New Curate" (A Story gathered from the Leaves of an Old Diary), by [illegible] P. A. Sheehan, Boston, 1900, P.P. [illegible] Doneraile, Co. Cork.

[2] "The physician sees in the body of man the material structure by which alone the known operations of the mind of man are possible in this world; the organs by which alone he can work his earthly work, whether it be the work which he shares in common with the beast of the field or the work through which he can enter into conscious relation to his unapproachable Creator; the frame by which, while bound down in an earthly charnel house, he lifts his eyes and strains his heart with yearning ineffable towards a higher nature and obeys the upward tending of impulses of affections strong unto death—affections so pure and so divine as to lose in the love of others even the consciousness of self."—Address on "The General Relations of Medicine to Modern Times," Sir Henry W. Acland, Oxford, 18[illegible].

A consideration of the characters and endowments of human cortical brain-cells and ganglia must ever excite our wonder and admiration. Amongst these we note their strange differentiation from their embryonic companions in the epiblast, the absence in them of secretive and reproductive functions, and the relative large size of their nuclei, those centres of nerve energy, invested with the power of storing, distributing, and regulating nerve force.[2] We know of no specialisation in function elsewhere in the body to compare with this, and beyond it we find the further endowments of psychical force and the capacity for the retention of memory.

For us, then, the cortical brain cells must take the first place of honour, and constitute the headstones of the temple of the body of man. Here, in the laminations of the grey matter, is the instrument of conscious mind, and in their intimate tissues lie the nerve and ganglion cells with their neurons whose structures afford the essential basis of all your special studies. We may regard other organs and viscera of the body from a more material side if we care to do so, but in the presence of a brain we are arrested by the thought that something immaterial had dwelt there which though independent of, yet had its interaction with, the vital energy which animated every individual cell and fibre of it. Human thought can project itself no further here and the scientific imagination may not penetrate this mystery. We can but regard this problem with the eye of faith and the assurance of a good hope, and re-trace our steps to contemplate the brain as the organ of mind and will. Our first consideration may surely be to recognise the fact that the majority of human beings are born into the world with well-formed and healthy brains. We may safely concede this in spite of the opinion that has been expressed to the effect that "most men are fools" and while recognising the varying degrees of brain power and mental capacity that exist even in members of civilised communities. This appears the more remarkable when we remember what serious defects result from minor flaws and limited morbid lesions in certain parts of the brain. It is astounding to realise that the histologist can in no way distinguish the physical characters pertaining respectively to the brain matter of a philosopher or a cow-herd, and yet how vastly different the endowments of each, both presumably sane and healthy. The brain, the organ of mind, is only healthy if its thinking parts work in harmonious and physiological order, and this relates essentially to a perfect nutrition and a normal cellular metabolism. There may be a sufficient supply of blood conveyed by healthy arteries, but that supply may be inadequate in quality or deficient in essentials for perfect nutrition. Again, it may be inappropriate by reason of something positively harmful contained in it. An altered metabolism occurs and the result is delirium or mental aberration. Were a necropsy possible in such a case there would almost certainly be nothing gross or macroscopical to reveal the nature of it. An ordinary examination of the brains of the insane has not seldom in the past been void of obvious lessons to the pathologist. Even now, when definite lesions are found, they are generally to be attributed to degenerations, which may be senile, even if prematurely so, or they are presumably dependent on chronic vascular congestion. An ordinary necropsy in cases of acute mania and of melancholia commonly reveals nothing abnormal. Grosser changes in the skull-cap and membranes, with hyperplasia of connective tissue, may be witnessed in cases of chronic insanity, and occasionally an acid reaction of the cerebro-spinal fluid. The most important lesions to be met with, however, are only detectable by a careful histological examination. Alterations in brain-cell function are found to be associated with what is now known as chromatolysis in which degeneration of the cell-plasm and finally of the nuclei occurs. This may be partial or very extensively diffused, and thus whole systems of neurons may become involved, their processes breaking off from the cell-body and degenerating. Mere naked-eye inspection does not reveal these intimate alterations, and till lately these minute alterations have been withheld from our observation. Hence it has hitherto often been difficult to realise what we now recognise as a fact that mental insanity is the result of brain disease. The probability is that we are now only gradually arriving at the *vera causa* of this and some other morbid states by the employment of new methods relating to the intimate metabolism of the tissues concerned, the chemical reactions which exist between the cell and its environment, and the environment and the cell. In this direction light may not improbably be shed on some of the problems which still puzzle the alienist. Our knowledge is now fairly complete respecting the grosser morbid changes affecting the brain and its investments, and we regard them as we do those of other organs, tracing the lesions to the elementary tissues in which they began; but we now require the services of the physiologist and chemist to carry on the studies respecting cellular dystrophies and the interactions of the intimate tissues of all parts of the body, for these studies, I may remark, are not strictly clinical.

Mental health must surely be dependent on the integrity of the brain-cells and neurons. Psychic endowment, no less than ordinary nerve energy, requires a normal condition of the machinery for its functions. The nuclei of the myriad cells[3] as physiological centres, their plasmic environment, the processes of the cell, their fibres and their collaterals must be intact, and the subtle metabolism at once securing nutrition and dispensing energy may not be disturbed or perverted without manifest disturbance of psychic and ordinary nervous rhythm.

I propose in this address to call your attention to some phases of mental disorder which depend on toxæmic states. These are now differentiated by the alienist, and it is only in recent times that their true nature has been unfolded. They have been long recognised as clinical features of disease, and the sources of them are as varied as are the separate toxic elements which induce them. Progress in physiological chemistry and bacteriology has now furnished us with the means to explain these conditions. The origin of these toxins is at least threefold. They may be generated in the body (auto-intoxicants) or by the malign working of microbes introduced from without, or they may arise by impregnation with organic poisons, or yet again result from the habits of alcoholism, chloralism, cocainism, and morphinism. In the majority of cases of insanity I suppose it will be conceded that there is a hereditary or inborn predisposition to the disorder, an instability or a tendency to this cerebral degeneration which may remain latent until conditions arise which are potent to elicit the break-down.[4] In the class of mental disorders we are now to consider there may or may not be this inherited fault of brain tissue. In many instances of toxic insanity we have to deal with persons who are already predisposed to mental instability, but in other cases a previously normal brain may be so damaged by toxic influences as to manifest aberration. We have long recognised the toxic effects on the nervous system of the altered metabolism induced by renal inadequacy in Bright's disease in the varied forms of uræmia, in that strange variety of autotoxy due to inability of the hepatic and muscular tissues to hold carbohydrate in reserve, resulting in diabetic coma, and that variety which depends on acute atrophy of the liver. We can now understand how these auto-intoxications act in disturbing the harmony of intimate brain cell metabolism. Their effects are as certain as are those of poisons directly introduced by the mouth or under the skin. The chemical functions of the brain-cell are disordered in precisely the same manner. In the ordinary practice of medicine we are familiar with states of delirium and mental aberration in the course of the various fevers and in pneumonia. Recognising these as infective disorders we now know that we are dealing with the toxic effects of invading parasites, and that amongst the manifold expressions of their presence are nervous or brain symptoms. *These are frequent* in pneumonia and strangely so when the pulmonary apex is involved. The reason for this is to me inscrutable, and I can only conceive that it results from some special local nervous relations which have hitherto escaped the recognition of the physiologists. With respect both to pneumonia[5] and the various fevers I have to add that a careful inquiry in cases where grave nervous or mental symptoms have supervened has almost always revealed the existence of personal or family neuropathic taint. Puerperal insanity occupies precisely the same position, and inquiries in these cases show that about one-half of them occur in women of neurotic or insane proclivity. Toxic influences naturally affect them more readily and with greater gravity.[6] The insanity of lactation probably owns a different cause and may be attributed to debility and imperfect nutrition, acting probably in many cases upon an originally unstable brain. What has been termed "post-operative insanity," due to infective influence, together with shock or exhaustion, and occurring within a few days after operation, may be similarly classified, although Mr. C. T. Dent is of the opinion that heredity of brain weakness plays but a small part in these cases, and that some of them apparently result from the influences of the anæsthetic agents employed or from iodoform impregnation.

---

[2] "We have no evidence to show that regeneration of nerve cells can take place in the higher vertebrates, but there is some evidence in favour of the view that all the nerve cells of the adult body are present in a rudimentary form at birth."—Dr. Mott, F.R.S., Croonian Lectures, Royal College of Physicians of London, 1900, Lecture I., p. 24.

[3] It has been calculated that there are not fewer than 600,000,000 nerve-cells in the human brain, and these do not multiply after birth.

[4] "Strictly speaking, it is the tendency to nervous disease rather than the disease itself which is inherited. ...... The neuropath may be conceived to possess in some portion of his nervous system communities, groups, and systems of neurons, either of defective durability or with an inherited low potential, readily becoming exhausted, and especially liable to functional depression, and which under the influence of contributory factors, such as toxic conditions of the blood or undue stress, undergo premature degeneration. To explain the inherited neuropathic tendency morphologically we may suppose that there is an inherent defect in the germinal plasm which is concerned in the formation of the neurons."—Dr. Mott, op. cit., Lecture III., p. 113.

No clearer evidence of the influence of auto-intoxication is afforded than that which results in aberrant cerebration in some cases of gout. The patient generates his own toxin in his tissues and the effects are recognised in the form of stupor, delirium with delusions, and excitement, sometimes as melancholia, such symptoms lasting occasionally for days or for many weeks, and yielding to some overt metastatic gouty development, generally articular, or to an anti-gouty medication, with complete recovery. In enteric, typhus, and rheumatic fevers, erysipelas, cholera, influenza, diphtheria, and scarlet fever we have examples of distinct toxic infections, producing their specific lesions and amongst them damage to cortical brain-cells leading to various grades of mental aberration, some of these ultimately leading to serious results, especially in cases where any predisposition to brain-degeneration or insanity exists These conditions were brought to the notice of the profession 36 years ago by Sir Herman Weber in a careful paper[7] in which he described the peculiarities of the mental states observed after the crisis had occurred in most of the acute diseases just mentioned. He laid much stress on the condition of shock and collapse which so often accompanies crises and on the associated cardiac debility which doubtless plays a considerable part in the phenomena. The time was not then ripe for the suggestion that toxic influences were concerned. The slow recovery, especially after prolonged attacks, with relapses, of enteric fever is due to the extreme wasting of the body generally, and the starvation of brain-cells in particular I would mention the peculiar loss of speech, or inability to speak, which occurs in some of these cases, several weeks (from five to eight) elapsing sometimes in which not one word is uttered.[8] We may notice a degree of this during the active stage of chorea which I have long distinctly regarded as due to rheumatic toxæmia in the majority of instances and a consequent perverted cortical brain-cell metabolism.[9] Additional proof in support of this view has lately been afforded by the careful researches of Dr. F. J. Poynton and Dr. A. Paine, which have demonstrated apparently the specific diplococcus of true rheumatism.[10]

The malign cerebral distempers due to influenza are very definite and have been well studied in the last epidemics of this plague. We find that all forms of insanity may result from it, and although there is reason to believe that in most instances of their occurrence there is an underlying neurotic proclivity, it is certain that the specific influenzal toxin affects the nervous system very gravely in most cases. According to Dr. John Turner all forms of acute mania are probably of toxic origin, affecting widely-spread areas of brain tissue, and he finds what he considers additional evidence in favour of this view that there is commonly associated in fatal cases a fatty degeneration of the liver.[11] The condition of myxœdema sometimes leads to brain symptoms such as instability, delusions, mania, and melancholia the result both in adults, and in the form of sporadic cretinism, of altered metabolism from deficient thyroidal influences. General paralysis is now regarded as coming into the category of auto intoxications. Syphilis, as its common antecedent, does not, however, provide the toxin, and we must therefore view its part in the etiology as leading to progressive degenerative nervous changes which in turn so modify the intimate metabolism of the tissues as to set free toxic elements. Alcoholic and other excesses are also antecedents in other cases, and sometimes lead impregnation is reckoned as the etiological factor. In cases of juvenile general paralysis congenital syphilis figures to the extent of at least 80 per cent, according to Dr. F. W. Mott, and he regards the malady as essentially due to the effect of syphilis on the germinal plasms of one or both parents. Jaundice as an autotoxic condition is accompanied sometimes by mental depression and hallucinations. I have, however, known xanthopsy to occur without any delusions in catarrhal jaundice.

We may next refer to toxæmic states induced by impregnation of the system with certain organic poisons, of which lead is certainly the most frequent and important source. This subject has been very fully studied. In many cases of saturnine encephalopathy we have to deal with compound conditions the result of possible syphilitic taint, together with chronic alcoholism. The fact that lead impregnation is related to the induction in many cases of gouty manifestations still further complicates the problem, and no less, too, the damaging effect of it on arterial and renal tissues has to be fairly considered in all such instances. The researches of Nissl, Oliver, and Robert Jones and others have now made plain for us the nature of the damage wrought upon the nervous system by this metal. We have to conceive that by degrees a saturation occurs, and chemical changes proceed in the brain and ganglionic cells whereby new compounds are formed within them. We might almost regard these, I think, as a formation of a chemical lead soap or a molecular combination of neural fat with a saturnine base. Again, we have to bear in mind the insoluble salt formed by uric acid with lead. Albeit the changes noted may not always be due to direct chemical influence, for saturnine encephalopathy may occur and no lead be detected in the brain, as shown by Oliver. Like other poisons, lead has a selective power in alighting upon and damaging tissues. Interference with normal metabolism in the cellular plasm, either by direct poisoning or by molecular chemical compounds of a fixed character interfering with function, may well lead to secondary and sclerous changes in the neurons. These, again, may be noxiously affected by freshly formed autotoxins resulting from such impaired cellular nutrition. We are not now concerned with the specific forms of saturnine neuritis which are well ascertained to exist and to produce characteristic symptoms. The whole question of lead encephalopathy is therefore a very complex one. It is, however, certain that many cerebral distempers may issue from it, such as mania, melancholia, dementia with epilepsy, and stupor amounting to coma. Some of these conditions occur after very short exposure to lead impregnation Whether general paralysis is ever strictly due to the specific influence of the poison is not yet quite determined. To be certain in the matter one must be able to eliminate the possibility of syphilitic and alcoholic influence. I am disposed to agree with Dr. Savage that saturnine taint is at least capable of inducing this condition and may do so.

---

[5] Cerebral symptoms in pneumonia may be dependent on grosser lesions than those due to brain-cell intoxication, as when pneumococcal meningitis forms part of the disorder.

[6] I am fortified in this opinion by Dr Savage's experience which affords proof that persons neurotically disposed are more than others vulnerable to the influence of specific infection.

With greater frequency than lead impregnation, we have to deal with alcohol as a poison introduced from without. We recognise the abuse of this as an active destroyer of nervous matter and vascular textures, and recent researches plainly indicate the damage done to the brain cells and neurons and the perverse metabolism which is entailed by it. The conditions displayed under the varieties of subacute and acute alcoholism with delusions, mania, epileptiform attacks, and dementia are unfortunately only too familiar to all of us.

Lastly, we have to note the mental aberrations due to the vicious use of agents such as morphine, chloral hydrate, paraldehyde, ether, and cocaine, and to remark concerning all of them that their abuse increases in frequency with what we are pleased to call the advance of knowledge and civilisation. That our profession is in part to blame for some of this mischief I entertain little doubt. The resort to these and similar agents under conditions which hardly justify their employment and which might often be met by other and simpler therapeutic measures has often led to habits of secret intoxication by patients who indulge in them. The frequent handing over of hypodermic syringes and these poisons to nurses is also to be blamed. The too ready sale of such agents by pharmacists and other tradesmen is a matter so serious that it now calls for some special legislation to restrict it. The danger lies in the special seduction of such agents for women and persons with unstable brains, and no care and precaution can be too great in prescribing for them We are all familiar with the disastrous results of yielding to the cravings for hypnotics and sedatives, and know too well our impotency to do any permanent good in the great majority of such cases. We certainly find that the average patient is singularly intolerant of any pain in these days, and that he clamours for relief at any cost. Our forefathers and foremothers had to suffer more than we do, and I am not sure that they were always the worse for it They certainly escaped the modern terrors of morphinism, chloralism, and cocainism, and the women of those days bravely endured their catamenial discomforts without recourse to stupefiants. I think a good deal of plainer living and higher thinking would avail much to abolish the too common resort to anodynes which unhappily now prevails so largely in several strata of society both in this and other countries.

In conclusion, we note that the various toxic agents which gain admission to the circulation exercise, as we might expect, their specific actions upon the several tissues of the body and manifest elective affinities for particular systems of neurons. We find in brain diseases, as in other morbid states, that the symptoms are the result not seldom of mixed infections and are not always to be ascribed to any one toxin. There is often, indeed, a vicious circle of conditions, as is well seen in some cases of general paralysis, lead poisoning, and alcoholism, where several factors are clearly combined in the production of the successive phenomena, in such a series as primary cell intoxication, with the result of perverted nutrition and plasmic metabolism, with the production of new toxins—e.g., choline and neurine—and decay of their systems of neurons, the exudation and the subsequent sclerosis on the part of the vessels. The student of morbid cerebral anatomy has now to reckon with all these conditions, and the clinical psychologist has to determine, if he can, the relation of them to the different forms of mental distemper. Those fields of study remain as yet much unexplored, but they are already being occupied by stalwart investigators, amongst whom I will claim a distinguished place for our countrymen Mott and Bevan Lewis. The knowledge already gained respecting the insanity of toxæmia cannot fail to prove useful for the purposes of treatment. We readily recognise how entirely preventable are most of these. Poisoning by lead, syphilis, alcohol, morphine, and fashionable anodynes is certainly preventable. The toxins formerly attendant on surgical interference are now practically abolished, while methods of treatment are gradually coming into use which encourage us to hope that we may overcome, or at least modify, the malign effects of such as induce the several infective diseases. We can now better understand than we did how purgatives and eliminants are often of use in dispersing some forms of mental distemper.

The views which now open out before us in respect of the pathogenic relations of toxæmic insanity would almost appear to justify a return to the older conceptions of humoral pathology. I am not concerned in this matter to take up any particular position dogmatically either as a humoralist or purely neural pathologist. I think that our duty is to find the facts, and then to apply them in building up our pathological doctrines. As time goes on it becomes necessary to keep an open mind and to change our views accordingly as modern research throws light on abstruse points. In the meantime I will venture to suggest that for the conditions we have been considering to-day we may consider them as dominated by a pathological doctrine to which we may fairly apply the term "neuro-humoral." By solid advances of knowledge and by revelations of fresh aspects of truth legitimate medicine alone makes progress. Many of you are now engaged in building up on sure foundations an important part of the great fabric of medicine, and some of us who 30 years ago imagined that small progress was being made with this particular work are now satisfied that it is assuming in your hands stateliness and dignity, and that it no less affords evidence of durability. I repeat that I have ventured to address you to-day from the standpoint of general medicine because general medicine most surely includes your special work. It would be bad for medicine and worse for you were such not the case. Some of us, indeed, could wish we were drawn closer together clinically in our great hospitals where our students commonly see little else than the beginnings or the transitory phases of mental aberration. But we urge them to fill up this gap in their education by attendance on lectures and practice, and in my own school we have full equipment and arrangements for this purpose. Let me add, lastly, that we fully recognise the debt which psychological medicine in this country owes to your association and we regard with full sympathy and interest your energy and your constant progress.

Presidential Address

ON

MOUTH-BREATHING AND ITS RELATION TO DISEASES OF THE THROAT, EAR, NOSE, AND ACCESSORY CAVITIES.

Delivered before the British Laryngological, Rhinological, and Otological Association on Nov. 9th, 1900,

BY MAYO COLLIER, M.S. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

MR. PAST PRESIDENT AND GENTLEMEN,—In acknowledging the honour you have done me by electing me as your President a mingled feeling of satisfaction and anxiety is apparent to me—satisfaction that things have so befallen me that you should consider me worthy to preside over your deliberations and anxiety that the debt I owe you in return may be poorly and inadequately repaid. It is the custom, not only in this society, but in other learned societies, for the incoming president to launch himself into power by delivering a lecture on some important subject connected more or less with the aims and objects of the society over which he presides. It is the first penalty you exact from him in return for the greatness you have bestowed upon him. I assure you this is a penalty not easy to pay. I have chosen a subject to address you on to-day that has aroused, and is likely to arouse, not only in this country but in America and the continent, considerable interest and controversy. It was more or less the subject for special discussion at the recent Ipswich meeting of the British Medical Association and it is a subject that has been discussed and animadverted upon by every degree of intelligence, including the many new recruits to the ever-increasing army of rhinologists and several distinguished members of our sister society in America, and, strange to say, it has even exercised the mind of a Past President of our own Royal College of Surgeons of England. Without ear-marking or criticising these various opinions I would take the liberty to-day, as your President, of placing before you my personal convictions, the result of a fairly extensive study of this subject for the past 18 years.

The text of my address to you to day is the relation and bearing of mouth-breathing, or its equivalent nasal obstruction, on affections of the throat, ear, and nose, and accessory cavities, and incidentally I shall touch upon its responsibility for some cases of distortion of the *upper jaw* and palate and its effect upon the general health. Logic has taught us, and very properly too, not to make use of terms we cannot define. It is on the definition or standard of what is nasal obstruction and what is not that so much difference of *opinion exists and so much want of comprehension* and negation of fact occurs.

First, I would remind you that the nose is the upper part of the respiratory tract. It is as much an essential part of the respiratory tract as the larynx or trachea. Its proper patency and physiological activity are just as essential to the respiratory function as are the proper patency and physiological activity of the larynx and the trachea. It is the great laboratory for the preparation of the food for the lungs, in the same way as the mouth is the laboratory for the preparation of the food for the stomach. With this preface I pass on to evolve a definition or standard of nasal obstruction. I must ask you, if we are to follow this subject step by step, to go back with me and look at the anatomical condition of things in the normal body and the physics pertaining to these parts when in normal physiological activity. The nasal cavities are surrounded by rigid bony walls and separated from each other by a thin septum, partly cartilaginous and partly bony, into two equal and symmetrical cavities. Each cavity communicates in front *viâ* the external nose with the air and posteriorly each cavity opens into the cloaca of the pharynx and so becomes the highway to the larynx and lungs. If the nose be of no account to respiration surely the mouth would be a larger, easier, and more direct inlet and outlet for the air in its passage to and from the lungs. Why go by the outer circle when the inner *circle is shorter, broader, easier,* and more direct? The object attained by the air passing through the nose and not through the mouth is to insure its being warmed to close upon 100° F., moistened to saturation, and filtered from all irritating and injurious particles of dust suspended in the atmosphere. And this for very good reasons, for cold air at first contracts the vessels in the respiratory mucous membrane, but subsequently dilatation sets in with accompanying catarrh. Dry air inspissates the mucus in the narrower parts of the respiratory tract and so renders the functions of the ciliated epithelium nugatory, induces collections of inspissated mucus on parts, and so induces coughing to remove the *same*. The air should be filtered in order to get rid of foreign particles and so lessen the chances of the direct introduction of tubercle and other germs to the lungs.

The normal physiological function of respiration is performed unconsciously and repeated some 20,000 times in the 24 hours. *This rapid and frequent filling* and emptying of the lungs that follows the expansion and contraction of the chest wall is only rendered possible by maintaining the normal patency *of the upper respiratory tract*; any obstruction to inspiration would upset the normal frequency of respiration and cause dyspnœa. A normal nasal *respiratory tract* is one capable of conducting air to the lungs with sufficient rapidity to instantly make up the deficit and equilibrate the lessened tension of the air in the lungs caused by the sudden expansion of the chest cavity. A nasal respiratory tract not capable of supplying air to the lungs day and night at the normal rate of inspiration and without the consciousness of the individual is an abnormal and obstructed nasal respiratory tract and the owner of such may be said to suffer from nasal obstruction. In other words, the necessity of supplementing nasal respiration by oral respiration or mouth-breathing is proof of nasal obstruction. Any evidence of mouth-breathing by day or night, and more especially by night, is evidence of deficient nasal respiration and so evidence of nasal *obstruction*. *Mouth-breathing by* day or night is evidence also that the physiological functions of the nose—the warming, the moistening, and the filtering process so admirably performed by the nose—are more or less in abeyance and so lost to the respiratory function.

Depending, as our definition does, on these physiological facts connected with the nose we may logically expect that a case of complete nasal obstruction such as may be caused by polypi on both sides would present one or more of the following symptoms. A nose when thus completely obstructed would be *a typical case of mouth-breathing. In* the abstract it would be possible to state that, given a person in this condition, certain symptoms of affections of the nose, throat, ears, lungs, and general health would probably supervene. The patient would probably be deaf and might have a discharge from one or both ears. He would have a *sense of discomfort and fulness in the nose with at times a* copious discharge and marked intermittent headaches. He would probably have marked post nasal catarrh, some pharyngitis, and cough and dryness of the throat in the morning. Added to this he would be liable to winter cough and bronchitis *and more than likely to attacks of asthma*. The digestion would probably suffer, and this again would induce a condition of neurasthenia and a feeling of something being wrong. Few of us present would refuse to admit that such a case of nasal obstruction as I have indicated might, and probably would, have one or more or all the symptoms enumerated as a direct result of the mouth-breathing.

Such being the symptoms which we clinically find in mouth-breathers it will be as well at this point to study the underlying physical basis on which they depend. The first question that presents itself is: When the air passes to the lungs *viâ* the mouth and not *viâ* the nose, what is the physical and pathological effect, if any, upon the nasal cavities and nose proper? I am well aware that although the nasal respiratory tract may be quite patent and adequate for normal respiratory purposes that voluntarily one can ignore this passage and breathe entirely by the mouth.

We will, therefore, first study the effect of mouth-breathing on an unobstructed nose. Under these circumstances what is the physical condition of the nasal respiratory passages? or, in other words, what is the effect of short-circuiting the respiratory tract? *In the first place, the physiological* functions of the nasal mucous membrane are in abeyance and consequently the air passes into the throat, the larynx, and the lungs much in the same condition as that in which it entered the portals of the mouth—that is to say, more or less dry and cold. The pathological effect of this may be, as we have seen, catarrh of the pharynx and larynx associated with cough and other unpleasant conditions. Has the passage of the air to the lungs *viâ* the mouth any other effect? I maintain that it has. It has a physical as well as a pathological effect. The fact that the nose is temporarily put out of gear or in a state of disuse absolves the dilator muscles of the nose from their functions. They no longer dilate during each act of inspiration and there is consequently a tendency of the wings of the nose to collapse. The weakest point is that part not stiffened with cartilage and is opposite the junction of the vestibule with the nasal cavity proper. *In mouth-breathers there is a marked pit or depression* on the alæ of the nose at this spot. This point may be compared to the rima glottidis in the larynx. It is the narrowest part of the nasal respiratory tract and it is the one most easily *obstructed. The interior of the nose* may be made quite patent and healthy, and yet collapse of *the nose from disuse may remain* and cause complete obstruction. The dimple on the outer aspect of the wing of the nose is diagnostic of the condition and pathognomonic of mouth-breathing. Long continued mouth-breathing or disuse of the nasal respiratory functions begets more or less complete atrophy of the muscles and tissues of the external nose with collapse of the alæ and gives a sharp and pointed expression to the features. I am of opinion, then, that mouth-breathing may induce or cause nasal obstruction from disuse or collapse of the nose valve.

The next proposition is: Does oral respiration or mouth-breathing produce any effect upon the interior of the nasal cavities? Undoubtedly it does. The air on its way to the larynx passes the opening into the naso-pharynx and nasal chambers and according *to a well-known law of physics* abstracts part of their contents. This, with a normal anterior nasal opening would be rapidly repaid and the tension equilibrated. Not so in cases of long-continued mouth-breathing where atrophy and collapse of the nasal *valve has set in*. The portion of air *abstracted* is in this case not adequately repaid; it is either too long in arriving or too little in amount, and the tension is not equilibrated, so that flushing of the whole mucous lining takes place from unsupported intra-vascular pressure. A Seigle's aspirator, as used for the ear, will afford you an excellent example and proof of this. Having properly fixed the instrument into the ear, on compressing the ball even the thick non-vascular lining membrane of the auditory canal is seen to grow pale. On allowing the ball to expand the whole lining membrane becomes a bright red The same thing occurs in the nose where the lining membrane is highly vascular and the vessels are thin-walled and the cellular tissue is lax and abundant. The abstraction of the smallest quantity of air from the nasal chambers and post-nasal space by the stream of air on its way to the lungs *viâ* the mouth, if not instantly compensated by a corresponding inflow from the outside air *viâ* the anterior nares, will cause a lessening of the tension of the air in the nose and accessory cavities. This lessened tension will be responded to by the lining membrane of the nose and accessory cavities as a general redness or flushing of the parts, and this will occur, of course, in direct proportion to the degree of rarefaction. This I hold to be a physical fact and upon the recognition of this fundamental physical fact rests the whole science and treatment of affections of the throat, ear, nose, and accessory cavities

I have taken a condition of things that does not exist in nature—namely, mouth-breathing with a perfectly healthy and physiologically adequate external nose and nasal chambers—and I have shown that even in this impossible and theoretical condition of things, with an unobstructed and healthy nasal tract, the effect and tendency of mouth-breathing is to induce not only anterior nasal obstruction by collapse of the nose valve, but general lessened capacity or obstruction from swelling and engorgement of the spongy and mucous lining of the nose and accessory cavities. I have described to you the collapsed, atrophied, pointed, and pinched nose of the mouth-breather. One other physical alteration is often apparent. The mouth-breather, in order to keep open the oral slit, partly raises the upper lip and in doing so uses a muscle (the levator labii superioris alæque nasi), and so involuntarily and unconsciously raises and arches the lower border of the wings of the nose. This disfigurement is very apparent in some cases of nasal obstruction and can be altered and done away with by curing the nasal obstruction and using the nose and not the mouth as the respiratory inlet. The peculiar arrangement and formation of the external nose has never been sufficiently recognised nor has the fact of its being a valve regulated and presided over by several distinct and more or less powerful muscles been taken into consideration in the diagnosis and treatment of disease of the nasal chambers. If you go to the Zoological Gardens and watch the seals and sea-horses swimming you will observe that before diving these animals completely close the nasal opening by the sphincters of the nose and widely open it by the dilators when arriving at the surface. These same muscles are present in the human nose and are none the less important in regulating the capacity of the portals of the respiratory tract. One may frequently observe in cases of hemiplegia that on the hemiplegic side of the face the wing of the nose is collapsed, and consequently that that side of the nose is obstructed and lost to the respiratory function. In deep chloroform narcosis and some head injuries nasal respiration is usually in abeyance from loss of power in the dilators of the nose.

Now to make matters clear we will sum up my contentions so far: (1) that mouth-breathing, if persisted in even in the hypothetical condition of a healthy and patent nose, would ultimately induce anterior nasal obstruction from atrophy following disuse of the nose valve; (2) that this would be followed by swelling of the lining membrane of the nose and accessory cavities from vascular dilatation; and (3) that this again would lessen the capacity of the nasal respiratory tract and tend to set up nasal obstruction. A vicious cycle is set up. Mouth-breathing tends to obstruct the nose and this very obstruction maintains and continues the mouth-breathing.

Beyond the fact that the external nose itself is liable under certain conditions to be a source of obstruction to nasal respiration, does the normal condition or arrangement of the clothing or lining of the rigid walls of the nasal chambers account for the ease with which the nasal cavities may become obstructed and the nasal respiratory function lessened or placed in abeyance? Although the framework of the nasal chambers is of bone and is admirably fitted to maintain the cavity and capacity of these chambers the necessity of placing within them an organ capable of performing the various physiological functions of the nose discounts the nose to some extent as the main respiratory inlet. We have lining these cavities and their various ledges and recesses a mucous membrane at once remarkable for its histological characters and physiological functions, and varying according to the part of the nasal chamber it may happen to line. In the vestibule the lining membrane is in a transition state between skin and mucous membrane; it secretes mucus, but still retains the hairs and the sebaceous glands proper to the skin. It is firm and closely adherent to the inlet of the nasal chambers and not liable to any appreciable swelling or turgescence. On entering the nasal cavity we find the mucous lining practically divided into two areas, the respiratory and olfactory. All that portion in a horizontal line above the lower border of the middle turbinal body is the olfactory area and the broader and more extensive surface below this line the respiratory area. Now, it is the respiratory area that we are more particularly interested in, and at the onset I would say that if it were not for presence in this area of the lower turbinal body we should hear little of nasal obstruction, and the occupation of the otologist, rhinologist, and laryngologist would be extremely limited. The lower turbinal bone extends from before backwards right in the path of the inspiratory stream and encroaches on the posterior and anterior nasal openings. It is covered with a membrane of peculiar constitution in so far as it is extremely thick, measuring at times from one-eighth to one-half of an inch. It has many vascular cavernous spaces in it resembling erectile tissues and is capable of sudden contraction and dilatation resembling true erectile organs. It so happens that this erectile tissue is more pronounced opposite the anterior and posterior openings of the nose and when distended it is capable of occluding both anterior and posterior openings completely and so capable of stopping nasal inspiration on one or both sides. A close study of the behaviour of this tissue in its various physiological and pathological conditions is a key to the understanding of the various phases of nasal obstruction and the many consequences arising therefrom. A perfectly healthy individual with a normally constituted nasal organ and placed always under normal circumstances would no doubt theoretically pass through the whole span of his existence without even a temporary obstruction to his nasal respiration such as is experienced in a common cold. When, however, one considers that such a condition of things does not and cannot exist—that the child in many cases is born with an affection of the mucous lining inherited from his parents, that his membrane may be affected by the various constitution and local complaints of its owner, that errors of diet, errors in environment, and errors in the constant variations and purity of the inhaled air all may have a disturbing influence on the proper physiological function of the turbinal body,—can we be surprised that the normal physiological working of this organ is frequently upset and ends in dilatation and obstruction? The air enters the nasal chambers some 20,000 times a day and should continue to do so without intermission during the whole life of the individual. The functional activy of the turbinal body is ceaseless and for its size exceeds the functional activity of any other organ of the body. It is calculated that two quarts of water a day are given up to the inspired air by this body and the lining of the nasal respiratory tract, and that all the air that enters the larynx, no matter what the outside temperature may be, is warmed to near the temperature of the body. This is no light duty. The pathological tendency of any organ is in direct proportion to its functional activity. Therefore, the pathological tendency to temporary and permanent dilatation or to engorgement from relaxation of vaso-motor tone and consequent hypertrophy is apparent. 99 cases out of every 100 of obstruction to the nose are due to this cause. The dilatation may be temporary, intermittent, or permanent, but still the tendency is there, the tone is lost, and nasal obstruction is the result.

Nothing is more common than for a patient to tell one that he is all right during the day when he is up and about, that he can breathe through the nose with ease and comfort, and can go upstairs or even take active exercise with the mouth shut. But directly he places his head on the pillow a very short time elapses before the nose is completely blocked. The explanation is simple. The tone of the tissue is so lax that the extra-venous pressure caused by the horizontal position is sufficient to dilate his turbinal bodies and stop his nasal respiration. Many a time have I been told by a patient that, when in bed even, the side of the nose which is lowest is the obstructed one and that on turning over the clear side becomes obstructed and the obstructed side clear. The effect of gravity through a range of four or five inches is sufficient to fill one side and free the other. Loss of tone of the turbinal bodies with or without hyperplasia is the commonest cause of nasal obstruction and this, like atrophy, may be strictly limited to one side, but in the great majority of cases both sides are affected and if one side be affected first the other side follows sooner or later. The recognition of the various degrees of these conditions is difficult, but still with a knowledge of what to look for and a proper subjective examination of the patient a correct diagnosis can be made.

To exemplify the points of the diagnosis I will give you an illustration of a case of atonic turbinal body which set up chronic posterior arytenoiditis, general pharyngitis, with granulations on the pharynx, indigestion, and general *deterioration of health. Quite lately, at the instigation of* Dr. G. Herschell, a gentleman living in France and who is a medical man brought his daughter to me for my opinion. The patient was about 18 years of age; she was of a sallow, muddy complexion and was spotted about the nose, chin, and mouth with acne indurata and acne rosacea. Her chief complaint was discomfort in the throat with cough continuing more or less all the time Her father had consulted several specialists in *Paris, Nice,* and *London,* with the result that most of them differed except on one point—and that one point was that the nose was perfectly healthy and unobstructed. They were all agreed so far; but they could not account for the constant "hemming" cough, just as if it were to clear some little thing away, the general over-moisture and vascularity of the throat, the tendency to sore-throat and to catch cold, and the indigestion and general want of tone. Whatever they did or said they did not cure the patient's trouble or her father would not have brought her to me. I have stated that there was posterior arytenoiditis, general over-vascularity with increased moisture in the pharynx, and some post-nasal catarrh. If the nose was healthy and quite patent and its physiological functions properly performed, what was the cause of the condition of the pharynx and larynx? Every effect has a cause—a patient does not get into this condition without good reason. It was not from syphilis, or tubercle, or gout, or alcohol, or smoking, or anything direct that one could make out. Moreover, it baffled all attempts at treatment by these various specialists; it continued; it was not cured, and why? It was a case of nasal obstruction, more especially at night. True, during the day, when up and about, the nose was clear, and when I examined it there was ample room for nasal respiration, but on cross-examination the patient admitted that her mouth and tongue were dry in the morning, that the discomfort of the cough was worse till she had taken food, and when I mentioned it she said that she had noticed that the nose was not clear at night. I did not rely upon the patient's statement entirely nor did I arrive at my diagnosis by the process of exclusion. I examined the nose; and what did I find? Well, in the first place, there was then ample room for nasal respiration. In no sense could one say that the nose was obstructed. The mucous lining of the nose was of a liver-red colour, with inspissated mucus in patches at various points indicating general congestion of the interior. On the septum opposite to each lower turbinal body was a deep groove or sulcus running from before backwards, its concavity corresponding accurately with the convexity of the turbinal body. There could be no doubt that the turbinal body had formed that groove and when distended it rested and accurately filled that groove. No further evidence was required. I ordered a mild alkaline antiseptic wash for a week. I then with the galvano-cautery pinned down the most prominent parts of the turbinal body to prevent it swelling much, in the way that a button is put on the seat of a chair, and with the help of a little chloride of zinc spray to the larynx sent this patient back to France practically cured in less than one month from the commencement of treatment. This was, then, undoubtedly a case of nocturnal nasal obstruction. The congestion of the nose, the post-nasal space, and the pharynx was started and maintained by the laboured inspiration necessary in these cases. Laboured inspiration means delay in compensating the tension of the air in the respiratory tract and this means vascular dilatation from unsupported intra-vascular pressure. I let in the air with the galvano-cautery, the tension was rapidly equilibrated and the vascular turgescence quickly subsided, the consequent over-secretion disappeared, and the arytenoid cartilages were no longer irritated by the constant dribbling of mucus over their surface into the laryngeal box. The hemming cough was no longer requisite to drive the secretion out again. Mucus in large quantities no longer passed into the stomach to impede digestion and the tone and general condition of the patient improved. This is the history of 99 out of every 100 cases of laryngeal catarrhs, huskiness and morning cough, sore and uncomfortable throat, the tendency to catch cold, and the general catarrhal *condition of the upper respiratory* tract. It all means mouth-breathing from nasal obstruction.

Unfortunately, the effects of atony and dilatation of the turbinal body such as I have endeavoured to place before you are not limited to the respiratory tract proper. We have passing out from the walls of the nose and naso-pharynx certain passages or openings communicating with cavities and chambers of considerable importance. *These chambers or cavities* are one and all *culs-de-sac* and communicate only with the nose or naso-pharynx, and that by in most cases extremely small openings. Each cavity is lined by mucous membrane continuous with that of the nose and is liable to be affected by the same pathological and physical conditions as the nose. Affections of the frontal, ethmoidal, sphenoidal, and maxillary sinuses may be originated or kept up by obstructive conditions of the nose. Catarrh may spread into one or any of these cavities. The opening into the cavity becomes obstructed and the products of catarrh accumulate and may form an abscess. Take the tympanic cavity as the best and commonest instance of this state of things. Nasal obstruction in these cases is fatal to a speedy restoration and cure. The very physical condition of nasal obstruction enhances and keeps up the occlusion of the only outlet to the discharges. In the case of the tympanic cavity it empties itself, as a rule, by perforating the tympanic membrane. But in the case of the frontal and maxillary sinuses the walls are bony and greater difficulty is experienced in getting rid of the contents. Whatever surgical procedure you adopt to empty the contents your first object should be to restore the patency of the natural outlet into the nose and see that outlet is maintained by freely ventilating the nose. A case of ear discharge will not get well unless you restore the natural patency of the Eustachian tube.

I will go one step further. I maintain that obstruction to nasal respiration may set up a rarefaction of the air contained in each of these cavities and cause congestion of the lining membrane and a possible outpour of fluid and blockage of the natural vent, although there be no previous disease or catarrh present. Take the tympanic cavity, where we can see the process developing. Blockage of the opening of the Eustachian tubes leads to deafness, which means that the air is absorbed by the lining of the closed cavity and the drumhead is driven in by the unsupported atmospheric pressure. An examination of the drumhead will now show no fluid present, but in 24 hours or 48 hours if the obstruction be maintained and air be not supplied to the tympanic cavity and the intra-vascular pressure is not equilibrated, fluid is poured out and marked vascularity is apparent down the handle of the malleus and in the neighbourhood of the short process. Occlusion of the frontal and antral openings is followed by the same result. As long as the nose continues to be blocked the deafness will remain. Treatment directed to restore the patency of the nose will restore the patency of the Eustachian tube and the hearing will suddenly return. The difficulty of treating an acute rhinitis is that the occlusion set up by the congestion is the prime *factor* in maintaining the congestion from the necessity of carrying on respiration by the supplemental respiratory opening the mouth. If you can only let air into the nose by any artificial means you will cure the rhinitis in half the time. I maintain, then, that the key to the prevention and treatment of all diseases of the accessory cavities of the nose, including the tympanic cavity, is to maintain the natural physiological condition of the nose and see that its respiratory capacity is sufficient to rapidly equilibrate the air in the respiratory tract during inspiration. I cannot consume your time by giving you illustrations, but you must believe me when I say that my note-books are teeming with cases that support my contentions to the letter.

In chronic deafness with discharges and tinnitus it is just as important to see that there is a free inlet of air to the respiratory passages as in the acute cases. *Chronic deafness,* or what is known as "dry catarrh" (a more ludicrous term could not well be invented), is nothing more or less than chronic Eustachian obstruction due in the great majority of mention it. The choking and coughing on taking fluids, along with the presence of some bronchitis, made me think that the child ought to be fed through a tube, but this did not prove to be necessary. It is well, according to Collins,[27] to delay using the tube as long as it is safe to do so. The danger of food passing into the air passages is, however, a real one. Stress is laid upon it by several writers, including Mackenzie,[28] Gee,[29] Oppenheim,[30] and Maingault.[31] Mr. Rock has recently given me notes of a case in which death resulted in two days' time from the entrance of food into the larynx in a case of diphtheritic palsy. There was present a large amount of membrane in this case. It was stated by Bowman[32] that cases in which there was dense and widely distributed membrane were most surely followed by paralysis. In 53 out of Goodall's[33] 125 cases much exudation was present. If a severe local lesion such as would lead to a large amount of exudation is likely to be followed by a correspondingly severe intoxication, then the frequent association of much exudation and paralysis is readily understood.

CASE 5.—A man, aged 34 years came to the out-patient department of the Leeds Infirmary in October, 1899, and gave the following history. He had severe diphtheria in June, 1899. He was away from work for seven weeks. He then worked for four weeks when he was again obliged to give it up. Fluids regurgitated through the nose after the attack. When he went away after the illness he was a little weak in the legs, but there was no unsteadiness until after he resumed his work. It was this unsteadiness which compelled him to give up his work on the second occasion. The patient was undoubtedly unsteady in walking. Romberg's symptom was distinctly present. The knee heel symptom could also be obtained. There was not the least doubt about the presence of ataxia in the legs. The pupils reacted to light and accommodation. The knee-jerks were absent. There were no bladder symptoms and no pains. Unfortunately, no note was made about sensation, but I believe that it was found unaffected. The patient was improving. He was at his worst in September. He continued further to improve and was eventually lost sight of.

The course of the disease in this case was peculiar as there was a considerable interval between the first paralytic symptoms and the ataxia. The patient was quite clear about his history. He had to relinquish his work on the second occasion on account of the incoördination which was a new symptom to him. There is the same difficulty in understanding how such new symptoms as the above should appear at some interval after the onset of the attack as there is in understanding how relapses as in Case 3 occur, or how a considerable time may elapse between the primary attack and the onset of the paralysis. There was no risk of mistaking this case for one of early tabes dorsalis. It is strange that a difference of opinion should exist as to the frequency with which paralysis follows diphtheria in the adult. Osler[34] and Landouzy, quoted by Goodall,[35] maintain that paralysis follows relatively more often upon the diphtheria of the adult than that of the child. Bowman,[36] quoted by Ross and Bury, has only met with rare instances in the adult which have not been followed by paralysis. Foord Caiger,[37] however, says that young children are more frequently affected than older ones.

CASE 6.—A boy, aged seven years, was brought to the out-patient room of the Leeds Infirmary in October, 1899. He had diphtheria six weeks previously. Fluids regurgitated shortly after the attack. He had not been injected. There was unsteadiness in gait. The child walked with his legs wide apart. He swayed when the eyes were closed and the feet were placed together. No knee-jerks could be obtained. The boy steadily improved so that when seen in the following April the incoördination had entirely disappeared and fluids did not regurgitate. I saw him a few weeks ago and he was quite well. His knee-jerks had returned.

This was a case in which ataxia was the most prominent feature.

Albuminuria and diphtheritic paralysis.—Albuminuria was present in Cases 1, 2, and 3. Unfortunately, the urine was not examined in Cases 4, 5, and 6. The considerable frequency of albuminuria in diphtheria is universally admitted. It is usually estimated as present in from one-half to two-thirds of the cases. The proportion is larger in fatal than in non-fatal cases. Thus H. Mackenzie[38] put it down as occurring in 76 per cent. of the former and in 49 per cent. of the latter. It is also more frequent in the paralytic than non-paralytic cases. Thus in Goodall's cases[39] it was noted in 88 per cent. of the former and only in 30 per cent. of the latter. Of course, it is possible, as Mackenzie remarks, that cases of diphtheria with albuminuria are likely to be kept more carefully under observation than other cases, but this will not account for the considerable discrepancy between the figures. An increase in the albuminuria has even been noticed at the time of the onset of the paralysis, as in Trousseau's well-known case.[40] The significance of albuminuria in diphtheria is important in considering its relation if any to the paralysis. It is very generally looked upon as an expression of the intensity of the intoxication, as Goodall,[41] Tirard,[42] Mackenzie,[43] and others mention. If the paralysis is a toxic symptom then, other things being equal, it would be expected to occur more frequently in cases where the intensity of the intoxication is greatest, that is, in cases in which albuminuria is also most likely to be present. Even if albuminuria is an indication of the severity of the intoxication it does not of course follow that it is an exact measure of the degree of intoxication. It is not, therefore, necessary to hold that the larger the amount of albumin present the more likely is the patient to develop paralysis. Thus Bowman[44] states that there is no real relation between the amount of albumin and the occurrence of paralysis. In Goodall's cases the amount of albumin present was very variable both in different cases and in the same case at different times. Yet Goodall[45] thinks that the more persistent the albuminuria and the greater the quantity, the more severe the case and the more likely are paralysis and cardiac irregularity to follow. The question has been discussed as to whether the paralytic symptoms are not really a manifestation of uræmia. Trousseau[46] long ago pointed out that the nervous accidents in diphtheria do not resemble the symptoms of uræmia and that they may occur in cases in which there is no albumin present. Maingault,[47] in his excellent description of diphtheritic paralysis, says that there is no relation of cause and effect between diphtheritic albuminuria and the paralytic accidents. Cadet de Gassicourt[48] also agrees in this statement. It certainly occurred to me when I heard of the death of Case 1 as to whether the child might not have died from uræmia, but neither Mr. Woods nor I thought that it was so. Of the vomiting occasionally seen in diphtheritic paralysis and present in Case 2 Mackenzie[49] says there are two reasons against its being the result of uræmia—viz., (1) it occurs, though rarely, where the urine is free from albumin; and (2) it is associated with other symptoms of cardiac failure. Gee,[50] however, says that vomiting is in most cases associated with an affection of the kidney. The urine is albuminous and scanty and even entirely suppressed. The patient, however, retains consciousness and convulsions rarely precede death. B. E. Myers[51] further states that the general nervous symptoms are convulsions, drowsiness, delirium rarely and restlessness frequently. We may apparently conclude that diphtheritic albuminuria has no other relation to diphtheritic paralysis than that both complications are more prone to occur where the diphtheritic intoxication is most intense. The question is not considered here as to whether kidneys damaged by a toxic nephritis are not more likely to lead to the retention within the body of the paralysis-producing poisons than would happen with healthy kidneys.

Ataxia in diphtheritic paralysis.—Ataxia was present in Cases 1, 5, and 6. It is now very generally recognised that diphtheritic paralysis is due to an affection of the peripheral nerves, although slight lesions have been occasionally found in the spinal cord. Quite recently Playfair and Rainy[52] have published a case with slight lesions in the spinal motor-cells and none in the nerves, and Rainy[53] has induced changes in the motor-cells by the injection of diphtheria toxin into rabbits. Since Déjerine's classical paper[54] on pseudo-tabes the possible occurrence of ataxia in diseases of the peripheral nerves has been everywhere admitted Long before any exact knowledge was obtained in regard to the pathology of diphtheritic paralysis a certain clumsiness in movement and an uncertain gait were noted by early writers on this subject. Trousseau was one of the first to call attention to it. In 1877 Rumpf[55] recorded a case from Erb's clinic in which the ataxia was very pronounced and he refers to similar cases recorded by Grainger Stewart[56] and Foot[57] The ataxia is nearly always combined with more or less paresis Some authors, such as Baginsky,[58] Rumpf,[59] and G. Stewart,[60] state that the ataxia appears first and then later the weakness. Of course, the weakness would tend to mask the ataxia. It is quite true that it is very unusual to find in diphtheritic paralysis the degree of disorderly movements with the flinging, stamping gait so commonly seen in tabes, but this is no reason why slighter degrees of incoordination should not be admitted. Babinski,[61] in his excellent article on neuritis, thinks that the term "ataxia" has been used too loosely in connexion with peripheral neuritis. He argues that mere weakness of certain groups of muscles—such, for instance, as the muscles of the back of the thigh in addition to the extensors of the foot—might give rise to a gait that had many resemblances to the true tabetic gait. He refers to the fewness of cases of multiple neuritis with the true tabetic gait which have been recorded and thinks that in a case reported by Jaccoud there must have been spinal cord lesions as well. This, however, would not invalidate the contention that typical ataxia may occur in diphtheritic paralysis. The ataxia may be very widespread, as in the case very carefully noted and recorded by Buzzard, in which the clumsiness of movement even extended to the lips. In some cases the ataxia has been of a reeling character, so that there was danger of mistaking it for cerebellar ataxia (Ashby and Wright[62] and Mackenzie[63]) Here probably the ataxia had extended to the trunk muscles.

Ataxia is supposed to be largely due to disturbance of the muscular sense. Von Leyden and Goldscheider[64] say that the integrity of the sensory sphere is necessary for the coördination of movement. Thus, the occurrence of sensory changes in diphtheritic paralysis, especially with ataxia, becomes a matter of some interest Jacobi[65] says that there are in some cases sensitive changes such as to cause ataxia. He no doubt includes here the muscular sense. Lloyd[66] speaks of diphtheritic pseudo tabes under the sensory type of multiple neuritis where the muscular sense is abolished. The changes in sensation are usually slight in diphtheritic paralysis They appear often to be limited to the ends of the extremities, as in Mott's case[67] In some cases there is *only subjective alteration in sensation Thus,* I have notes of a case of an adult in whom there was a severe faucial lesion but relatively few general symptoms, due probably to the serum treatment. During convalescence she complained of numbness and pins and needles in the feet and legs, The onset of paralysis was feared, but she never had anything *more than a very slight* regurgitation of fluid *into the nose* In some cases where there is ataxia there may be no alteration in sensation. This was so in Rumpf's case[68] previously alluded to. On the other hand, in Hansemann's[69] case, where there was considerable ataxia, there was also impairment of sensation, including that of location. Disturbances of sensation, as unfortunately happened in my cases, do not receive the attention which they deserve, partly on account of the difficulty of investigating them in children

Diagnosis—There is rarely any real difficulty in recognising diphtheritic paralysis. The only cases in which doubt may arise are those in which the nature of the sore-throat has been overlooked Cases with very slight initial lesions have ultimately come to bear some resemblance to tabes dorsalis, but the pupillary symptoms, disturbance of the bladder functions, pains, mode of onset and course should make the distinction comparatively easy. Gowers,[70] Buzzard,[71] Oppenheim,[72] Baginsky,[73] Grainger Stewart,[74] and others refer to this possible *difficulty in diagnosis,* but Déjerine appears to think that it may be exaggerated. A very unusual example of exceptional difficulty is recorded by Morton Prince.[75] A medical student inoculated himself while making a necropsy on a case of diphtheria. The wound became inflamed and 10 days later there was difficulty in swallowing and regurgitation of fluid through the nose. Some months later he presented some of the symptoms of early tabes. The pupils, however, reacted normally and there were no pains or bladder disturbance. The patient recovered completely, but not until after absolute rest in bed had been had recourse to It has been stated that paralysis may be the first manifestation of diphtheria (Cadet de Gassicourt[76] and Henoch[77]). Henoch, however, adds that it is more likely that the initial lesion has been overlooked. The diagnosis might in such cases be very difficult if the diphtheritic paralysis pursued at all an anomalous course. Lindsay Steven[78] mentions that there might be some difficulty in distinguishing between Landry's paralysis and diphtheria, and one or two authors, such as Maingault,[79] say that hysteria might also give rise to errors in diagnosis.

Prognosis—The question may first be discussed as to whether it is possible to predict the occurrence of paralysis. Apart from what has been previously mentioned as regards the kind of cases in which paralysis is more likely to supervene, it has also been stated that anæsthesia of the palate may enable the observer to foretell the onset of the paralysis some days before it appears. Cadet de Gassicourt[80] pointed this out in reference to laryngeal diphtheria. It is true that Gee[81] emphasises the fact that paralysis is very rare after laryngeal diphtheria, no doubt because the patients die before it has time to develop All authors do not take the same view as Gee and unquestionably the serum treatment, by increasing the number of recoveries from laryngeal diphtheria, has also increased the number of cases which are likely to develop paralysis. In the first place it may be stated that recovery from the paralysis will occur *if life is preserved, although* several months may elapse before the patient is well In general the prognosis of diphtheritic paralysis is good, yet the number of deaths amounts to from 12 to 15 per cent. Cadet de Gassicourt[82] and Mott[83] think that it is more fatal than is usually believed. There is reason to think that in some epidemics the *mortality is higher than in others* Among a group of 275 cases reported by Myers[84] 80 died, or nearly 30 per cent In considering more closely the question of prognosis it is well to divide diphtheritic paralysis into (1) the localised; (2) the general; and (3) the cardio-pulmonary forms The prognosis of the localised and even the *generalised forms is good,* but that of the *cardio pulmonary* form is bad and generally very bad. This cardio pulmonary form may not only exist by itself but may supervene upon the generalised and even the localised forms. Hence an element of uncertainty is introduced even among the milder forms of the affection. In Cadet de Gassicourt's[85] 15 cases of the cardio-pulmonary type 14 died; in 10 of these cases the paralysis was otherwise limited to the palate. Case 1 in the earlier stages did not seem to be really serious, yet fatal respiratory symptoms soon supervened. On the other hand, some of the worst cases, especially with threatening respiratory symptoms, may recover, so that both Osler[86] and Lloyd[87] say that the outlook is not always so hopeless as the patient's appearance would indicate This fact was well illustrated in Case 2 Mr. Woodcock, Dr Ballantyne, and myself all thought the case quite hopeless, and yet recovery ensued.

In the cardio pulmonary form death may occur by paralysis of the heart or respiration, including in the latter broncho-pneumonia resulting from the respiratory paralysis. Sometimes, owing to paralysis of the depressors of the epiglottis, food may get into the air-passages and even produce sudden death, as in Maingault's case,[88] or a fatal broncho-pneumonia. In cases of diphtheritic paralysis it is mention it. The choking and coughing on taking fluids, along with the presence of some bronchitis, made me think that the child ought to be fed through a tube, but this did not prove to be necessary. It is well, according to Collins,[27] to delay using the tube as long as it is safe to do so. The danger of food passing into the air passages is, however, a real one. Stress is laid upon it by several writers, including Mackenzie,[28] Gee,[29] Oppenheim,[30] and Maingault.[31] Mr. Rock has recently given me notes of a case in which death resulted in two days' time from the entrance of food into the larynx in a case of diphtheritic palsy. There was present a large amount of membrane in this case It was stated by Bowman[32] that cases in which there was dense and widely distributed membrane were most surely followed by paralysis. In 53 out of Goodall's [33] 125 cases much exudation was present. If a severe local lesion such as would lead to a large amount of exudation is likely to be followed by a correspondingly severe intoxication, then the frequent association of much exudation and paralysis is readily understood.

CASE 5.—A man, aged 34 years came to the out-patient department of the Leeds Infirmary in October, 1899, and gave the following history. He had severe diphtheria in June, 1899 He was away from work for seven weeks. He then worked for four weeks when he was again obliged to give it up. Fluids regurgitated through the nose after the attack. When he went away after the illness he was a little weak in the legs, but there was no unsteadiness until after he resumed his work. It was this unsteadiness which compelled him to give up his work on the second occasion. The patient was undoubtedly unsteady in walking. Romberg's symptom was distinctly present. The knee heel symptom could also be obtained. There was not the least doubt about the presence of ataxia in the legs. The pupils reacted to light and accommodation. The knee-jerks were absent. There were no bladder symptoms and no pains. Unfortunately, no note was made about sensation, but I believe that it was found unaffected. The patient was improving. He was at his worst in September. He continued further to improve and was eventually lost sight of.

The course of the disease in this case was peculiar as there was a considerable interval between the first paralytic symptoms and the ataxia. The patient was quite clear about his history. He had to relinquish his work on the second occasion on account of the incoordination which was a new symptom to him. There is the same difficulty in understanding how such new symptoms as the above should appear at some interval after the onset of the attack as there is in understanding how relapses as in Case 3 occur, or how a considerable time may elapse between the primary attack and the onset of the paralysis. There was no risk of mistaking this case for one of early tabes dorsalis. It is strange that a difference of opinion should exist as to the frequency with which paralysis follows diphtheria in the adult. Osler[34] and Landouzy, quoted by Goodall,[35] maintain that paralysis follows relatively more often upon the diphtheria of the adult than that of the child. Bowman,[36] quoted by Ross and Bury, has only met with rare instances in the adult which have not been followed by paralysis Foord Caiger,[37] however, says that young children are more frequently affected than older ones.

CASE 6—A boy, aged seven years, was brought to the out-patient room of the Leeds Infirmary in October, 1899. He had diphtheria six weeks previously. Fluids regurgitated shortly after the attack. He had not been injected. There was unsteadiness in gait. The child walked with his legs wide apart. He swayed when the eyes were closed and the feet were placed together. No knee-jerks could be obtained. The boy steadily improved so that when seen in the following April the incoordination had entirely disappeared and fluids did not regurgitate. I saw him a few weeks ago and he was quite well. His knee-jerks had returned.

This was a case in which ataxia was the most prominent feature.

Albuminuria and diphtheritic paralysis.—Albuminuria was present in Cases 1, 2, and 3. Unfortunately, the urine was not examined in Cases 4, 5, and 6 The considerable frequency of albuminuria in diphtheria is universally admitted. It is usually estimated as present in from one-half to two-thirds of the cases. The proportion is larger in fatal than in non-fatal cases. Thus H. Mackenzie[38] put it down as occurring in 76 per cent. of the former and in 49 per cent. of the latter. It is also more frequent in the paralytic than non-paralytic cases. Thus in Goodall's cases[39] it was noted in 88 per cent of the former and only in 30 per cent. of the latter. Of course, it is possible, as Mackenzie remarks, that cases of diphtheria with albuminuria are likely to be kept more carefully under observation than other cases, but this will not account for the considerable discrepancy between the figures. An increase in the albuminuria has even been noticed at the time of the onset of the paralysis, as in Trousseau's well-known case.[40] The significance of albuminuria in diphtheria is important in considering its relation if any to the paralysis. It is very generally looked upon as an expression of the intensity of the intoxication, as Goodall,[41] Tirard,[42] Mackenzie,[43] and others mention. If the paralysis is a toxic symptom then, other things being equal, it would be expected to occur more frequently in cases where the intensity of the intoxication is greatest, that is, in cases in which albuminuria is also most likely to be present. Even if albuminuria is an indication of the severity of the intoxication it does not of course follow that it is an exact measure of the degree of intoxication. It is not, therefore, necessary to hold that the larger the amount of albumin present the more likely is the patient to develop paralysis. Thus Bowman[44] states that there is no real relation between the amount of albumin and the occurrence of paralysis. In Goodall's cases the amount of albumin present was very variable both in different cases and in the same case at different times. Yet Goodall[45] thinks that the more persistent the albuminuria and the greater the quantity, the more severe the case and the more likely are paralysis and cardiac irregularity to follow. The question has been discussed as to whether the paralytic symptoms are not really a manifestation of uræmia. Trousseau[46] long ago pointed out that the nervous accidents in diphtheria do not resemble the symptoms of uræmia and that they may occur in cases in which there is no albumin present. Maingault,[47] in his excellent description of diphtheritic paralysis, says that there is no relation of cause and effect between diphtheritic albuminuria and the paralytic accidents. Cadet de Gassicourt[48] also agrees in this statement It certainly occurred to me when I heard of the death of Case 1 as to whether the child might not have died from uræmia, but neither Mr. Woods nor I thought that it was so. Of the vomiting occasionally seen in diphtheritic paralysis and present in Case 2 Mackenzie[49] says there are two reasons against its being the result of uræmia—viz, (1) it occurs, though rarely, where the urine is free from albumin; and (2) it is associated with other symptoms of cardiac failure. Gee,[50] however, says that vomiting is in most cases associated with an affection of the kidney. The urine is albuminous and scanty and even entirely suppressed. The patient, however, retains consciousness and convulsions rarely precede death. B. E. Myers[51] further states that the general nervous symptoms are convulsions, drowsiness, delirium rarely and restlessness frequently. We may apparently conclude that diphtheritic albuminuria has no other relation to diphtheritic paralysis than that both complications are more prone to occur where the diphtheritic intoxication is most intense. The question is not considered here as to whether kidneys damaged by a toxic nephritis are not more likely to lead to the retention within the body of the paralysis-producing poisons than would happen with healthy kidneys.

Ataxia in diphtheritic paralysis.—Ataxia was present in Cases 1, 5, and 6. It is now very generally recognised that diphtheritic paralysis is due to an affection of the peripheral nerves, although slight lesions have been occasionally found in the spinal cord. Quite recently Playfair and Rainy[52] have published a case with slight lesions in the spinal motor-cells and none in the nerves, and Rainy[53] has induced changes in the motor-cells by the injection of diphtheria toxin into rabbits. Since Déjerine's classical paper[54] on pseudo-tabes the possible *occurrence of ataxia in diseases* of the peripheral nerves has been everywhere admitted. Long before any exact knowledge was obtained in regard to the pathology of diphtheritic paralysis a certain clumsiness in movement and an uncertain gait were noted by early writers on this subject. Trousseau was one of the first to call attention to it. In 1877 Rumpf[55] recorded a case from Erb's clinic in which the ataxia was very pronounced and he refers to similar cases recorded by Grainger Stewart[56] and Foot[57] The ataxia is nearly always combined with more or less paresis Some authors, such as Baginsky,[58] Rumpf,[59] and G. Stewart,[60] state that the ataxia appears first and then later the weakness. Of course, the weakness would tend to mask the ataxia. It is quite true that it is very unusual to find in diphtheritic paralysis the degree of disorderly movements with the flinging, stamping gait so commonly seen in tabes, but this is no reason why slighter degrees of incoördination should not be admitted. Babinski,[61] in his excellent article on neuritis, thinks that the term "ataxia" has been used too loosely in connexion with peripheral neuritis. He argues that mere weakness of certain groups of muscles—such, for instance, as the muscles of the back of the thigh in addition to the extensors of the foot—might give rise to a gait that had many resemblances to the true tabetic gait. He refers to the fewness of cases of multiple neuritis with the true tabetic gait which have been recorded and thinks that in a case reported by Jaccoud there must have been spinal cord lesions as well. This, however, would not invalidate the contention that typical ataxia may occur in diphtheritic paralysis. The ataxia may be very widespread, as in the case very carefully noted and recorded by Buzzard, in which the clumsiness of movement even extended to the lips. In some cases the ataxia has been of a reeling character, so that there was danger of mistaking it for cerebellar ataxia (Ashby and Wright[62] and Mackenzie[63]). Here probably the ataxia had extended to the trunk muscles.

Ataxia is supposed to be largely due to disturbance of the muscular sense. Von Leyden and Goldscheider[64] say that the integrity of the sensory sphere is necessary for the coördination of movement. Thus, the occurrence of sensory changes in diphtheritic paralysis, especially with ataxia, becomes a matter of some interest. Jacobi[65] says that there are in some cases sensitive changes such as to cause ataxia He no doubt includes here the muscular sense. Lloyd[66] speaks of diphtheritic pseudo tabes under the sensory type of multiple neuritis where the muscular sense is abolished. The changes in sensation are usually slight in diphtheritic paralysis. They appear often to be limited to the ends of the extremities, as in Mott's case.[67] In some cases there is only subjective alteration in sensation. Thus, I have notes of a case of an adult in whom there was a severe faucial lesion but relatively few general symptoms, due probably to the serum treatment. During convalescence she complained of numbness and pins and needles in the feet and legs. The onset of paralysis was feared, but she never had anything more than a very slight regurgitation of fluid into the nose. In some cases where there is ataxia there may be no alteration in sensation. This was so in Rumpf's case[68] previously alluded to. On the other hand, in Hausemann's[69] case, where there was considerable ataxia, there was also impairment of sensation, including that of location. Disturbances of sensation, as unfortunately happened in my cases, do not receive the attention which they deserve, partly on account of the difficulty of investigating them in children.

Diagnosis —There is rarely any real difficulty in recognising diphtheritic paralysis. The only cases in which doubt may arise are those in which the nature of the sore-throat has been overlooked Cases with very slight initial lesions have ultimately come to bear some resemblance to tabes dorsalis, but the pupillary symptoms, disturbance of the bladder functions, pains, mode of onset and course should make the distinction comparatively easy. Gowers,[70] Buzzard,[71] *Oppenheim*,[72] Baginsky,[73] Grainger Stewart,[74] and others refer to this possible difficulty in diagnosis, but Déjerine appears to think that it may be exaggerated. A very unusual example of exceptional difficulty is recorded by Morton Prince.[75] A medical student inoculated himself while making a necropsy on a case of diphtheria. The wound became inflamed and 10 days later there was difficulty in swallowing and regurgitation of fluid through the nose. Some months later he presented some of the symptoms of early tabes. The pupils, however, reacted normally and there were no pains or bladder disturbance. The patient recovered completely, but not until after absolute rest in bed had been had recourse to It has been stated that paralysis may be the first manifestation of diphtheria (Cadet de Gassicourt[76] and Henoch[77]). Henoch, however, adds that it is more likely that the initial lesion has been overlooked. The diagnosis might in such cases be very difficult if the diphtheritic paralysis pursued at all an anomalous course. Lindsay Steven[78] mentions that there might be some difficulty in distinguishing between Landry's paralysis and diphtheria, and one or two authors, such as Maingault,[79] say that hysteria might also give rise to errors in diagnosis.

Prognosis —The question may first be discussed as to whether it is possible to predict the occurrence of paralysis. Apart from what has been previously mentioned as regards the kind of cases in which paralysis is more likely to supervene, it has also been stated that anæsthesia of the palate may enable the observer to foretell the onset of the paralysis some days before it appears. Cadet de Gassicourt[80] pointed this out in reference to laryngeal diphtheria. It is true that Gee[81] emphasises the fact that paralysis is very rare after laryngeal diphtheria, no doubt because the patients die before it has time to develop. All authors do not take the same view as Gee and unquestionably the serum treatment, by increasing the number of recoveries from laryngeal diphtheria, has also increased the number of cases which are likely to develop paralysis. In the first place it may be stated that recovery from the paralysis will occur if life is preserved, although several months may elapse before the patient is well. In general the prognosis of diphtheritic paralysis is good, yet the number of deaths amounts to from 12 to 15 per cent. Cadet de Gassicourt[82] and Mott[83] think that it is more fatal than is usually believed. There is reason to think that in some epidemics the mortality is higher than in others. Among a group of 275 cases reported by Myers[84] 80 died, or nearly 30 per cent. In considering more closely the question of prognosis it is well to divide diphtheritic paralysis into (1) the localised; (2) the general; and (3) the cardio-pulmonary forms. The prognosis of the localised and even the generalised forms is good, but that of the cardio pulmonary form is bad and generally very bad. This cardio-pulmonary form may not only exist by itself but may supervene upon the generalised and even the localised forms. Hence an element of uncertainty is introduced even among the milder forms of the affection. In Cadet de Gassicourt's[85] 15 cases of the cardio-pulmonary type 14 died; in 10 of these cases the paralysis was otherwise limited to the palate. Case 1 in the earlier stages did not seem to be really serious, yet fatal respiratory symptoms soon supervened. On the other hand, some of the worst cases, especially with threatening respiratory symptoms, may recover, so that both Osler[86] and Lloyd[87] say that the outlook is not always so hopeless as the patient's appearance would indicate This fact was well illustrated in Case 2. Mr. Woodcock, Dr. Ballantyne, and myself all thought the case quite hopeless, and yet recovery ensued.

In the cardio-pulmonary form death may occur by paralysis of the heart or respiration, including in the latter broncho-pneumonia resulting from the respiratory paralysis. Sometimes, owing to paralysis of the depressors of the epiglottis, food may get into the air-passages and even produce sudden death, as in Maingault's case,[88] or a fatal broncho-pneumonia. In cases of diphtheritic paralysis it is necessary to be on the look-out for any alteration in the pulse, such as infrequency, acceleration, and irregularity. Judson Bury[89] also states that the respiration may give warning of approaching danger. In Case 3, as mentioned above, the respiration became irregular at times. It was a disquieting symptom, but the patient recovered. Cardiac failure is not necessarily the result of an affection of the cardiac nerves. It may sometimes be due to an intense and acute degenerative myocarditis such as occurred in a case which I reported a few years ago.[90] Mott[91] has further shown that in such cases the cardiac nerves may be free from disease.

There are certain symptoms which various authors look upon as of evil import. Thus Dawson Williams[92] says that cases with paralysis of the cervical muscles or marked ataxia call for a guarded prognosis. Early and especially repeated vomiting (Gee[93] and Mackenzie[94]) is a bad sign. Very early appearance of the paralysis must give rise to considerable misgiving as regards the termination of the illness. Little further need be added upon the question of albuminuria in relation to prognosis. Case 2 with considerable albuminuria and severe paralysis recovered and Case 1 with albuminuria and apparently a less severe attack of paralysis died. Abercrombie[95] writing in 1881 described the occurrence of albuminuria in diphtheritic paralysis as a grave symptom. This statement would hardly apply where the albuminuria is slight. No doubt the presence of a considerable and persistent albuminuria would add to the gravity of the case. Other things being equal the prognosis of a case with albuminuria should be more serious than one without albuminuria, since the presence of albuminuria shows a more profound intoxication. Generally stated the prognosis as regards life is bad in the cardio-pulmonary type of diphtheritic paralysis; it is good in the localised and generalised forms, but some reserve must be expressed lest the paralysis extend to the heart or respiration. Cadet de Gassicourt[96] insists that this reserve must be made to include even mild cases of diphtheritic paralysis.

Treatment.—The first point in the treatment may very naturally be made to include the question as to whether anything can be done to prevent this formidable complication of diphtheria. Some authors strongly insist on the importance of rest. Thus Mott[97] says that paralysis is often the result of a neglect of proper treatment and rest during convalescence. The heart has been pointed out as specially liable to paralysis because it cannot rest. Collins[98] is convinced that many cases of diphtheritic neuritis would not occur if the period of convalescence were more carefully guarded. It seems to be a wise and almost imperative measure to insist upon rest, at any rate partial, until the time of the greatest incidence of paralysis is past (second, third, and fourth weeks)

I may here quote the conclusions drawn by Dr. F. Ransom[99] from a valuable experimental research conducted in Professor Behring's laboratory. He shows that paralysis may certainly be expected after intoxication with not less than one-fourth of the minimal fatal dose of toxin. With doses between one-fourth and one-eighth paralyses occur but are not constant, and below one-eighth no paralysis was noticed. The larger the dose of toxin the severer will be the paralysis if the animal survive long enough. If the paralysis is a toxic manifestation, as the experiments of Ransom and others certainly show that it is, then any treatment which antagonises this intoxication should on theoretical considerations at least lessen the liability to paralysis. It has been stated by some very reliable observers (Baginsky,[100] Goodall,[101] and Marsden[102]) that if the serum treatment were more generally adopted paralysis would be less frequent. If this could be definitely proved it would be a telling argument in favour of injecting every case of diphtheria, however slight. On the other hand, severe paralysis does occur in cases (Case 3) which have been injected and apparently sufficiently injected. Also Huber[103] states that treatment by antitoxin or otherwise has apparently no influence upon the subsequent development of paralysis. The remaining conclusions by Dr. Ransom bear very directly on this point. He continues: "Neutralised mixtures of toxins and antitoxins containing only about one lethal dose or less do not appear to cause paralysis. Antitoxin given 15 to 22 hours after intoxication with doses of toxin not greater than the lethal dose exercises a mollifying influence on the subsequent paralysis. This influence is more evident on smaller doses of toxin than on such as are but little less than the minimal fatal dose. Small doses of antitoxin have no evident effect in diminishing the paralysis." Dr. Ransom further adds: "Transferring these results to practice amongst human beings, we may expect liberal doses of antitoxin given early in the illness to influence favourably the subsequent paralysis, and this beneficial influence is likely to manifest itself not so much on the local paralysis (soft palate, &c.) as on such symptoms as failure of the heart. Severe cases are, *however, likely to be followed by some paralysis in spite of* even large doses of antitoxin." I set aside here purposely the question as to whether the serum treatment can be made responsible for the occurrence of paralysis, as I take it that there is no sort of reliable evidence, either clinical or experimental, in support of this view.

If rest is to be recommended in the hope of preventing the paralysis it is even of still greater importance in the treatment of this complication, both with the view of preventing its extension and in promoting recovery. Nearly all authors are in accord on this question of rest in the treatment of diphtheritic paralysis. On the least suspicion of the slightest implication of the heart absolute rest in the recumbent posture is essential. It may be well not even to let the patient feed himself. If symptoms of cardiac failure arise efforts must be made to counteract it—frequent and regular stimulation, subcutaneous injection of strychnine or sparteine (Comby),[104] ice to the præcordium (Collins),[105] galvanism, &c. Collins recommends faradaism judiciously employed. The value of electrical treatment in warding off alarming symptoms of cardiac failure is shown by a case related by Duchenne,[106] but the patient ultimately succumbed to respiratory paralysis. If the respiratory muscles fail, the faradaic current, inhalation of oxygen, and injection of strychnine may be tried. Respiratory movements may be artificially assisted. Huber also mentions tongue traction. If there is evidence of paralysis of the epiglottis (choking after food) the milk should be first thickened with isinglass (Mackenzie),[107] or the head may be bent backwards in swallowing (Cadet de Gassicourt).[108] If these fail then the tube must be used either through the nose or the mouth. Nutrient enemata may also be employed. During later convalescence massage and galvanism in short sittings and tonic remedies, including strychnine, may be useful. An American author (Mundorff[109]) suggests the treatment of these cases of paralysis by the injection of anti-diphtheritic serum and he relates two cases in support of his views.

Leeds.

THE DIAGNOSIS OF PLAGUE.

By W. C. HOSSACK, M.D. ABERD.,

DISTRICT MEDICAL OFFICER, CALCUTTA.

IN view of the sinister fact that the long-expected has at last happened and that the British Isles at the time of writing show a focus of indigenous plague in the city of Glasgow, a short notice on the diagnosis of plague from the practical point of view of one who has been working at it in India for the last three years may not be out of place. Two diametrically opposed views are constantly expressed on this subject: that nothing can be more clear, definite, and easy to recognise than plague, and that no disease is more difficult to follow in its multiform varieties. The fact is that both opinions are partly true. To one who has had practical experience of an epidemic of plague the majority of cases are as unmistakeable as fracture of the thigh would be; but a small proportion will remain, to come to a clear decision regarding which may tax to the utmost the powers of diagnosis of the practitioner, as may be gathered from the definite instances which later I will give. On the other hand, a man who is devoid of experience and has seen no plague, unless he is particularly on the alert too often fails as completely to recognise a perfectly typical case as would a herbalist if confronted with an incipient case of locomotor ataxy! The statement may sound alarming and may be regarded as a distinct slur on the profession, but unfortunately it is founded not on a little personal experience in Calcutta but on a survey of epidemics of plague in every country. In going over the records it will be found that almost every outbreak, whether in Oporto, Buenos Ayres, Bombay, or Calcutta, has been ushered in either by a series of unrecognised cases or, if they were recognised at the time, by an outburst of popular denial supported very often by men of distinct standing in the profession A very good example is to be found in the "Report on the Malignant Fever called Pali Plague," 1838 The medical men who investigated the disease on the spot were unanimous and uncompromising in their diagnosis of the disease as "Levantine plague," as it was called then, and their detailed reports are identical with the clinical records of the present epidemics in India But Dr. Ranken, secretary to the Bengal Medical Board, who prepared the general report sums up thus: "The affection of the glands is the sole peculiarity of the Pali disease as an Indian fever, and there are facts which prove that symptom to be no diagnostic or necessary attendant of the plague. The affection of the glands often does not appear in marked cases of the Egyptian pest, and it has been observed, however rarely, in all the types of fever known in Europe, North America, and the West Indies The Pali disease is therefore not plague in the sense of modern authors and teachers, implying its derivation directly or indirectly from Egypt or the Levant by specific contagion, but a fever which local causes produced and circumstances rendered malignant and infectious"

[109] Medical Record, 1896.

Many similar instances will be found noted in a paper by Professor W. J. Simpson in THE LANCET of April 14th, 1900 (p. 1063), and without going into detail it may be stated that they have been far from uncommon in Calcutta The latter are better left alone, but it may be permissible to cite a couple of cases as instancing how in their inexperience the very best men may fail to recognise the most clear and well-defined cases In investigating a case of illness I gathered from the contradictory and unreliable statements made by the friends of the patient that they had suspected the illness to be plague. When the case was followed up to one of the leading Government hospitals in Calcutta—one where a special plague ward had just been instituted—it was found to be a case of typical plague pneumonia, but the patient was lying in an ordinary ward with a diagnosis of fever with pneumonia The case had entirely escaped suspicion, though when attention was called to it the diagnosis of plague was made at once and the patient was removed to the plague ward Again, a leading surgeon, a man with an established European reputation, was called to see in consultation a typical case with parotid bubo He confirmed the diagnosis of the attending native physician—erysipelas. Some time afterwards he admitted his mistake and explained that in his inexperience he had thought it impossible for a case of plague to show so much cellulitic œdema round the gland. Similar instances might be multiplied indefinitely, but enough has been said to make it clear that until practical experience has been gained the average practitioner is very liable indeed to let the disease pass quite unrecognised. Unfortunately it is only during the period when he still has this experience to gain that it is so essential for him to recognise cases. It is of little use, comparatively, to recognise cases when an epidemic has got well started, because the almost universal experience in large cities has been that the disease spreads so widely and rapidly that the exhaustive application of preventive measures becomes almost impossible and the eradication of the disease entirely so But if the early cases are at once detected, if no case is allowed to pass unrecognised, then there is every prospect that if strict measures are rigidly enforced the disease may be prevented from gaining a foothold With this consideration in view the necessity will be understood for dwelling at length on clinical facts that to one with any knowledge of the disease will seem ridiculously plain and self evident.

GENERAL CHARACTERISTICS.

The disease may be defined as an acute epidemic septic disease due to bacillus pestis and generally characterised by the presence of buboes or glandular swellings. The word "septic" is used in its general application, regardless of whether the organisms themselves or only their products are circulating in the blood,[1] for the clinical entity called loosely by the word "sepsis" is one of the most universal and characteristic features of the disease and forms an excellent foundation from which to build up a complete picture of it. Think of the general characters of an acute case of puerperal septicæmia and you have an idea of the general characters of the typical case of plague Where buboes are not present—and this may be in a large proportion of the cases, amounting in the epidemic of 1900 in Calcutta to about 30 per cent. in my district—this acutely septic character is the chief basis of diagnosis. Where the septic characters are wanting or are little marked, as they are in a small proportion of cases, the bubo is generally sufficiently characteristic to guide the practitioner. Several varieties of the disease are described, but it must be borne in mind that the different types overlap so much that in individual cases one might be justified in classifying the case under almost any or all of the headings. The types recognised are as follows: (1) the bubonic, (2) the pneumonic, (3) the septic, (4) the intestinal, (5) the meningeal, and (6) the carbuncular. Before taking up these types in detail it will first be necessary to consider the diagnostic characteristics common to all. The onset of the disease is almost invariably sudden, without premonitory symptoms Very rarely I have seen the onset gradual, so that the patient could go about his business for a day or two. The intensity and rapidity of the course of the disease are such that excepting cholera there is hardly any other disease likely to produce so grave a general condition within so short a time The tongue is of considerable diagnostic value The characteristic feature is that while the dorsum is coated, the edges, the tip, and often the median raphe remain pink and clean, sometimes getting red and dry. The coating is at first rather thin and white as a rule. It may be yellowish and in severe cases it generally becomes brown. Whether white or brown the edges and the tip remain typical. When the last epidemic was at its height and cases were very rapidly fatal I several times saw tongues yellowish brown from the very onset, but this is exceptional and the silvery white tongue is the rule The pulse is the most valuable factor in diagnosis Over and over again it will put one on the track when confronted with an abnormal case with very mild general symptoms, for it is invariably fast and out of proportion to the general condition of the patient. A preliminary stage of fulness is sometimes described[2] but it is very evanescent and within a few hours the pulse becomes quick and feeble, 100 a minute in a mild case and 120 in the average case, and frequently up to 140 It is very compressible and it tends to become rapidly dicrotic and running. Intermittency is common and is generally a very fatal sign. Eventually it becomes difficult or impossible to count It is a pulse, in short, that almost from the very beginning indicates the presence of some acutely toxic condition, a pulse that might be expected towards the conclusion of a fatal attack of enteric fever rather than after an illness the duration of which is to be reckoned in hours. Though not so constant a feature as the rapid feeble pulse, muscular incoördination is very common and is of great diagnostic importance. The gait is staggering and drunken and the speech is thick, slow hesitating, blurred, and halting. Sometimes complete aphonia is met with during the illness. Captain Thompson, I M S, records seven cases of development of aphonia after convalescence[3] Early in the disease the face is drawn and anxious-looking and the corners of the mouth are drawn down in an expression of extreme weariness and pain. Later in the disease, or sometimes from the beginning, the face is blurred, heavy, stupid, and expressionless As to the mental condition of the patient, he is as a rule heavy, drowsy, stupid, and incapable of answering questions or of taking an interest in what is going on around him. He will put out his tongue, but only when he is shouted at This condition gradually deepens into stupor and coma. Delirium is generally present, especially at night, commonly it is low and muttering, but sometimes very violent The very early onset of the stupor or delirium is a valuable characteristic At the same time it must be remembered that it is by no means constant I have frequently heard the statement made: "Oh, it cannot have been plague, for he was conscious all along" I recall a case where the duration of illness was only 24 hours, and there was just time for the femoral bubo to begin to appear before the attack ran its course. Yet the patient, a child-wife, aged 13 years, put out her tongue and told me her name three minutes before she breathed her last. Her feet and hands were already cold, and she was *in articulo mortis.* Another case was seen on the sixth day of illness in the following condition: there was a large left axillary bubo, the pulse was 150, the temperature was 103° F., the breathing was stertorous, and liquid râles were heard from the bedside. Yet the patient was sufficiently clear mentally to recognise me as the plague medical officer, to make a last pitiful effort at concealment with the words, "I am all right; I am not ill at all," and to refuse to allow me to examine his chest. This was within a few hours of his death. Again I have seen an English-speaking Eurasian solicitor on the fifth day of his illness within 12 hours of his death perfectly conscious and rational. The femoral gland had begun to subside and his condition was such that the medical attendant thought the attack done with and demurred strongly when I gave an absolutely bad prognosis based on symptoms of pneumonia in both apices. The daughter of the patient was taken ill on the same day as the father and she died at the same hour, yet 12 hours before death she had been conscious and rational and her speech was unaffected, and the mother, complaining that she could not keep her in bed, asked me to talk to her and to scold her, while the sign of approaching death was written plainly in a distinctly intermittent pulse of 120. In this case, too, the femoral gland was beginning to subside and had lost its tenderness. Such cases are rather exceptional, but I have dwelt on them because it seems very generally to be held that a plague patient must necessarily show cerebral derangement and that if it is absent the case cannot be plague. This contention was the turning-point of a will case in Bombay. Conjunctival congestion is a very fairly constant feature. The whites of the eyes may look quite red, while at times they may only be muddy. It is of value particularly where one has to diagnose a case from the history solely. The temperature in plague is so irregular that it is of very little diagnostic value. It tends to be very high (from 103° to 105° F) but it is liable to irregular remissions particularly on the second or the third day. Recovery is generally by rapid lysis, rarely by crisis. The normal is generally reached from the fifth to the seventh day.

The Bubonic Type.

The typical plague bubo is, as a rule, remarked within 24 hours of the onset of the attack by pain, tenderness, and a gland from the size of a bean to that of a walnut, most commonly in the parotid, cervical, axillary, or inguinal region. Within 24 hours, as a rule, the gland can no longer be distinguished and is lost in a boggy œdematous swelling which varies, as a rule, from the size of an egg to that of a large orange. This swelling is generally painful and is always tender, sometimes acutely so. At times it may be hard and brawny, but the soft boggy feeling is most characteristic with no well-defined limits; occasionally, particularly in the cervical and parotid region, the swelling may be very diffuse, suggesting cellulitis or erysipelas. I have seen the whole of the triangles of the neck filled up. The skin over the bubo, which is at first normal in colour, may get dusky red, at first freely moveable over the swelling, but latterly incorporated with it as a rule.

The glands.—It may happen that the gland does not go on to form a bubo, but remains distinct and of moderate size; this is particularly so in the septic type. Chains of matted glands may be found. A practical point is that glands may be *deep*, particularly in the femoral region and may be overlooked unless carefully felt for with deep pressure. From their exquisite tenderness they will often thus be found. I have frequently seen a patient who was almost comatose and who could respond to no other stimulus start with a cry when pressure was made over the site of a gland too deep, perhaps, to be felt clearly. Another point is that the appearance of glands or of a bubo may be delayed. Captain Thompson says that 70 per cent. appear on the second day, 15 per cent. on the third day, 12 per cent. on the fourth day, 2 per cent. on the fifth day, and only 1 per cent. on the sixth day. I have seen one on the fifth day and one remarkable case on the tenth day. The patient had all the general symptoms—stupor, high temperature, &c.—but repeated examinations failed to reveal either glands or pneumonia till on the tenth day a typical femoral bubo developed.

Unusual site.—This should cause no difficulty, for buboes may be found practically wherever glands exist. Dr. McCabe Dallas records 31 different combinations of single or multiple buboes, not to speak of nine different combinations with pneumonia, and Captain Thompson records one in the right popliteal and the calf of the leg, one in the left popliteal, one in the right brachial, one in the right forearm, two in the scalp, and three in the mammary gland out of a total of 304 cases. Out of 193 cases observed directly I have noted one in the right pectoral fold, one in the left pectoral fold, one in the mamma, one in the right sub-occipital, two in the right testicle, and one in the symphysis pubis, and among cases investigated after death I have noted two in the testicle, one in the mamma, and one in the right elbow. The deep glands of the trunk, such as the lumbar, bronchial, and mesenteric glands, may be affected, but they are more of pathological than of clinical interest.

The Pneumonic Type.

Plague pneumonia may be primary or secondary, that is to say, appearing as a complication in a case with a bubo. It is so very liable to go undiagnosed that it is difficult to say what proportion of plague cases may be of this variety,[4] but after paying particular attention to the subject I came to the conclusion that it was about 30 per cent. of the 2237 cases in my district of Calcutta. Of the 194 cases actually observed no less than 32·48 per cent. showed respiratory symptoms. Of those 62 per cent. were primary pneumonia; in 25 per cent. it was doubtful whether it was primary or secondary, and in only 13 per cent. was it clearly secondary to buboes; 50 per cent. showed a bubo in addition to the pneumonia. Of the 64 cases only three (less than 5 per cent.) recovered, and one of those mainly, I think, as the result of an immediately antecedent plague inoculation. The figures as to the frequency of pneumonia may possibly be challenged, but as to its excessive mortality all are agreed. The leading and most diagnostic point about this variety is that while the general symptoms of the disease are exceptionally grave and exceptionally rapidly developed the local lung symptoms and the results of physical examination are so very slightly marked that they can often be detected only after a most careful examination. The disease, in short, is of an intensely septic type and the lungs show little of the signs of consolidation of ordinary pneumonia as a rule. In fact, many of the cases which I have called pneumonic might by another observer have been called septicæmic. In this connexion it may be noted that the returns for the Medical College Hospital, Calcutta, for 1898 showed that out of 98 cases 10 were pneumonic, 20 were septicæmic, and in four cases there were both buboes and pneumonia[5]—that is to say, that 30 per cent. of the total cases were non-bubonic. My figures for the epidemic of 1900 are 193 cases with 44 cases non-bubonic, but only 11 of these 44 were septicæmic. In reality the number of septicæmic cases should be even less, as I know that in some of them in a second examination I made out lung symptoms, but in the rush of work no record was made. The presumption from these figures is that Captain Evans, who compiled those returns, would have made some of my pneumonic cases septicæmic and *vice versâ*, but, at all events, this fact is brought out clearly, that in Calcutta the proportion of non-bubonic cases is very high. The precise designation is a matter of secondary importance, particularly as in his very valuable pathological report Captain Evans gives his opinion that plague pneumonia is due to infection from the blood rather than from the air-passages—that is to say, that the pneumonia is simply the expression of a septicæmia. The main facts pointing to a case being plague pneumonia, in addition to its generally septic character, which has already been sufficiently described under general symptoms, are as follows. Cough may be very slight and occasional. The breathing, taking into consideration the high temperature, is little hurried or laboured, and the ordinary pneumonic disproportion of pulse and respiration rate is reversed. The pulse is the rapid feeble septic pulse already described, probably 120 per minute. The sputum like the cough, tends to be very scanty and occasionally so much so that in very many of my cases there was no opportunity of seeing it. As a rule it is clear and mucoid, very like bronchitic sputum. Occasionally it may be faintly muco purulent. Rusty sputum I have only seen once, and it was welcome as I had just shown the case to a medical sceptic who on the strength of a first expectoration, bronchitic in character, had declared the case to be simple bronchitis. The rusty sputum came only after forced coughing. Blood in the sputum I have seen twice. In one case there was a history of almost hæmorrhage from the lung. Prune-juice sputum I have never seen.

[4] Major L. F. Childe, I.M.S , V. (1), p. 109

[5] Captain C. H. Evans, I.M.S., Plague Commissioners' Report, vol. i., p. 244.

Physical signs.—Very frequently on the first day or two of illness it will be found impossible to make out anything abnormal in the chest. Then will be found probably in one or both apices a small patch some two inches in diameter with bronchial breathing and increased vocal resonance and a few fine moist râles. Dulness on percussion, as a rule, is very faint, if made out at all. The rest of the lung will probably be normal, but an occasional râle or rhonchus may be made out. All the signs given may be very faint and over a very small area, but if present at all, however faintly, they may be taken, as far as my experience goes, as almost inevitably indicating a fatal result. So often has it been only after repeated examinations that such a patch has been found, and so liable is it to be overlooked, that I am inclined to call any case pneumonia as soon as I find cough present and to assume that the patch has either been overlooked or else is too deep in the lung to cause definite physical signs. The result of post-mortem examinations as recorded by Major Childe, Captain Evans, and others in their reports supports that view, patches of from the size of a walnut to that of a pea being described. Of course, at times the patches are widely distributed over the lungs and may form a consolidated mass over the greater part of one lobe giving clear physical signs, but in my experience this is not common. Other observers, while agreeing for the most part with my description, lay less stress on the paucity of physical signs and describe the sputum rather differently. Thus Major Lyons, I.M.S., says: "The expectoration is diagnostic from that of ordinary broncho-pneumonia, it being less viscid from the first, and early becomes profuse and watery and generally tinged with blood or reddish from admixture of blood."[6] Major Childe makes it "loose and free, coming up with the slightest cough, looking more like serum than mucus, and it was slightly pink, not rusty-yellow at all." "It is not always as described"; it may be "much less profuse," "and in some cases the presence of blood is a marked feature." Captain Thompson makes it "seromucoid, scanty, and occasionally tinged with blood." Dr. McCabe Dallas describes it similarly. All, however, note the comparative absence of dyspnœa. I have described a form noted in the epidemic of 1899 where the general symptoms were very mild, rather bronchitic in character, and only the excessive pulse-rate and the unexpected fatal termination gave the clue, but in the epidemic of 1900 such cases were not common.[7] The duration of these cases may be up to 10 days.

Bacteriological examination.—Major Childe states that cultures can always be obtained from the fluid from the trachea and bronchial tubes. Personally I have had little opportunity of testing this, as, in the words of Captain James, "none of us had time for laboratory or investigation work. The time of a plague medical officer is far too occupied for leisure for scientific research."[8] On the few occasions upon which I have tried to cultivate from sputum only mixed cultures from ordinary mouth organisms were recognisable.

THE SEPTIC TYPE.

This type of plague is best described as plague where neither glands, buboes, nor pneumonia can be detected. Major Childe describes a definite condition of multiple affection of the glands, but those are more likely to be detected in the post-mortem room than at the bedside. Moreover, they are to be found along with typical buboes.

THE INTESTINAL TYPE.

Less than 5 per cent of the investigated cases were of this type. They were generally registered as cholera, but the high fever and the bloody nature of the stools put this out of the question. Dr. E. C. Pettifer, my colleague, has seen a case with 30 motions a day and a bubo in addition. The diarrhœa in ordinary bubonic cases may be very marked. In District 10 in the epidemic of 1896-97 in Bombay the proportion of this type is put down as 3 per cent.[9] The stools are generally described as thin, yellow, and bad smelling. Major Gibbons, I.M.S., has described to me a case where the bowel on post-mortem examination was full of black blood. It is a very severe and rapid type as a rule, thereby distinguishing it from typhoid fever or dysentery; in cholera one would have the coldness, collapse, and rice-water stools.

THE CEREBRAL TYPE.

I have called this cerebral in preference to meningeal, as in so many cases where the symptoms would have led to the expectation of finding at the post-mortem examination gross meningeal or cerebral lesions none have been present. Sometimes, however, distinct signs of meningitis are present, according to Captain Thompson 0·66 per cent. He says: "The frequent presence of cerebral disturbance and the rarity of true meningeal inflammation would seem to prove that the symptoms depend on toxæmia."

THE CARBUNCULAR TYPE.

This type of plague is rare. In the last epidemic I only saw one case of it and in the previous epidemic only three cases. What struck me in most of those cases which I did see was the superficiality of the swelling and the fact that the induration was marginal rather than deep, also there were no deep excavating sloughs, but only a shallow widespread sloughing of the skin. Dr. K. C. Bose, C.I.E., has remarked the same thing. At the same time I have seen very deep excavation of the thigh in Calcutta and another huge excavation in the lumbar region in Poona. Captain Evans got cultures from a carbuncle on the face, but does not describe it. Our knowledge of this type is at present deficient, and our diagnosis must rest mainly on probability and the excessive gravity of the symptoms compared with the size of the carbuncle. One case of this type was seen by a number of medical men, the diagnosis of plague made by the district medical officer having been questioned. At least one of those gentlemen declared the man to be suffering from simple boil on the buttock, and all came to the conclusion that it was not plague. Nevertheless the man died within 24 hours.

DISEASES LIKELY TO BE CONFOUNDED WITH PLAGUE.

It must, in the first place, be remembered that there is hardly one of the specific fevers in which glandular swellings do not occasionally occur even if rarely and that in an epidemic of no matter what disease there is the liability to have abnormal and malignant cases of very short duration that approximate plague in general characters: for example, a case of measles with meningitis. In such cases probability must be taken into account. I shall only mention those diseases which have actually been mistaken for plague in Calcutta or have at least caused difficulty.

Puerperal fever.—Plague in pregnant women almost invariably causes abortion or premature delivery. The point to be noted, then, in puerperal fever is whether the fever has come on before the onset of labour: such a case must be looked upon as suspicious. Plague under such conditions is very liable to be overlooked.

Septicæmia.—In septicæmia the diagnosis is bacteriological or by probability.

Pyæmia.—I recall a case where even at the post-mortem examination the diagnosis was not clear whether it was pyæmia or plague, incipient pus formation being evident in the gland substance of the mamma and about the glands of the neck. Cultures settled that it was plague. Another case was diagnosed in hospital as pyæmia and sloughing of the scrotum, but I still maintain that it was plague for the following reason. With the onset of fever came a right axillary bubo. On the third day glands appeared in the left inguinal region and swelling of the left testicle. By this time the axillary bubo had almost entirely subsided. This rapid subsidence I have seen more than once in cases of multiple bubo, but it is highly improbable that a pyæmic swelling in a case like this, which went on to a fatal termination, would thus resolve.

Small-pox.—I have once diagnosed small-pox as plague and have twice seen it thus diagnosed. The advent of the eruption, of course, made the correct diagnosis clear.

Influenza.—The more malignant forms of influenza are extremely difficult to distinguish from plague without tubes for the leading characteristics of both diseases are the same. In both nervous disorders are predominant and in both the pneumonia is lobular and ill-defined; sweats are highly illness was only 24 hours, and there was just time for the femoral bubo to begin to appear before the attack ran its course. Yet the patient, a child-wife, aged 13 years, put out her tongue and told me her name three minutes before she breathed her last. Her feet and hands were already cold, and she was *in articulo mortis.* Another case was seen on the sixth day of illness in the following condition: there was a large left axillary bubo, the pulse was 150, the temperature was 103° F., the breathing was stertorous, and liquid râles were heard from the bedside. Yet the patient was sufficiently clear mentally to recognise me as the plague medical officer, to make a last pitiful effort at concealment with the words, "I am all right; I am not ill at all," and to refuse to allow me to examine his chest. This was within a few hours of his death. Again I have seen an English-speaking Eurasian solicitor on the fifth day of his illness within 12 hours of his death perfectly conscious and rational. The femoral gland had begun to subside and his condition was such that the medical attendant thought the attack done with and demurred strongly when I gave an absolutely bad prognosis based on symptoms of pneumonia in both apices. The daughter of the patient was taken ill on the same day as the father and she died at the same hour, yet 12 hours before death she had been conscious and rational and her speech was unaffected, and the mother, complaining that she could not keep her in bed, asked me to talk to her and to scold her, while the sign of approaching death was written plainly in a distinctly intermittent pulse of 120. In this case, too, the femoral gland was beginning to subside and had lost its tenderness. Such cases are rather exceptional, but I have dwelt on them because it seems very generally to be held that a plague patient must necessarily show cerebral derangement and that if it is absent the case cannot be plague. This contention was the turning-point of a will case in Bombay. Conjunctival congestion is a very fairly constant feature. The whites of the eyes may look quite red, while at times they may only be muddy. It is of value particularly where one has to diagnose a case from the history solely. The temperature in plague is so irregular that it is of very little diagnostic value. It tends to be very high (from 103° to 105° F.) but it is liable to irregular remissions particularly on the second or the third day. Recovery is generally by rapid lysis, rarely by crisis. The normal is generally reached from the fifth to the seventh day.

THE BUBONIC TYPE.

The typical plague bubo is, as a rule, remarked within 24 hours of the onset of the attack by pain, tenderness, and a gland from the size of a bean to that of a walnut, most commonly in the parotid, cervical, axillary, or inguinal region. Within 24 hours, as a rule, the gland can no longer be distinguished and is lost in a boggy œdematous swelling which varies, as a rule, from the size of an egg to that of a large orange. This swelling is generally painful and is always tender, sometimes acutely so. At times it may be hard and brawny, but the soft boggy feeling is most characteristic with no well-defined limits; occasionally, particularly in the cervical and parotid region, the swelling may be very diffuse, suggesting cellulitis or erysipelas. I have seen the whole of the triangles of the neck filled up. The skin over the bubo, which is at first normal in colour, may get dusky red, at first freely moveable over the swelling, but latterly incorporated with it as a rule.

The glands.—It may happen that the gland does not go on to form a bubo, but remains distinct and of moderate size; this is particularly so in the septic type. Chains of matted glands may be found. A practical point is that glands may be *deep*, particularly in the femoral region and may be overlooked unless carefully felt for with deep pressure. From their exquisite tenderness they will often thus be found. I have frequently seen a patient who was almost comatose and who could respond to no other stimulus start with a cry when pressure was made over the site of a gland too deep, perhaps, to be felt clearly. Another point is that the appearance of glands or of a bubo may be delayed. Captain Thompson says that 70 per cent. appear on the second day, 15 per cent. on the third day, 12 per cent. on the fourth day, 2 per cent. on the fifth day, and only 1 per cent. on the sixth day. I have seen one on the fifth day and one remarkable case on the tenth day. The patient had all the general symptoms—stupor, high temperature, &c.—but repeated examinations failed to reveal either glands or pneumonia till on the tenth day a typical femoral bubo developed.

Unusual site.—This should cause no difficulty, for buboes may be found practically wherever glands exist. Dr. McCabe Dallas records 31 different combinations of single or multiple buboes, not to speak of nine different combinations with pneumonia, and Captain Thompson records one in the right popliteal and the calf of the leg, one in the left popliteal, one in the right brachial, one in the right forearm, two in the scalp, and three in the mammary gland out of a total of 304 cases. Out of 193 cases observed directly I have noted one in the right pectoral fold, one in the left pectoral fold, one in the mamma, one in the right sub-occipital, two in the right testicle, and one in the symphysis pubis, and among cases investigated after death I have noted two in the testicle, one in the mamma, and one in the right elbow. The deep glands of the trunk, such as the lumbar, bronchial, and mesenteric glands, may be affected, but they are more of pathological than of clinical interest.

THE PNEUMONIC TYPE.

Plague pneumonia may be primary or secondary, that is to say, appearing as a complication in a case with a bubo. It is so very liable to go undiagnosed that it is difficult to say what proportion of plague cases may be of this variety,[4] but after paying particular attention to the subject I came to the conclusion that it was about 30 per cent. of the 2237 cases in my district of Calcutta. Of the 194 cases actually observed no less than 32.48 per cent. showed respiratory symptoms. Of those 62 per cent. were primary pneumonia; in 25 per cent. it was doubtful whether it was primary or secondary, and in only 13 per cent. was it clearly secondary to buboes; 50 per cent. showed a bubo in addition to the pneumonia. Of the 64 cases only three (less than 5 per cent.) recovered, and one of those mainly, I think, as the result of an immediately antecedent plague inoculation. The figures as to the frequency of pneumonia may possibly be challenged, but as to its excessive mortality all are agreed. The leading and most diagnostic point about this variety is that while the general symptoms of the disease are exceptionally grave and exceptionally rapidly developed the local lung symptoms and the results of physical examination are so very slightly marked that they can often be detected only after a most careful examination. The disease, in short, is of an intensely septic type and the lungs show little of the signs of consolidation of ordinary pneumonia as a rule. In fact, many of the cases which I have called pneumonic might by another observer have been called septicæmic. In this connexion it may be noted that the returns for the Medical College Hospital, Calcutta, for 1898 showed that out of 98 cases 10 were pneumonic, 20 were septicæmic, and in four cases there were both buboes and pneumonia[5]—that is to say, that 30 per cent. of the total cases were non-bubonic. My figures for the epidemic of 1900 are 193 cases with 44 cases non-bubonic, but only 11 of these 44 were septicæmic. In reality the number of septicæmic cases should be even less, as I know that in some of them in a second examination I made out lung symptoms, but in the rush of work no record was made. The presumption from these figures is that Captain Evans, who compiled those returns, would have made some of my pneumonic cases septicæmic and *vice versâ*, but, at all events, this fact is brought out clearly, that in Calcutta the proportion of non-bubonic cases is very high. The precise designation is a matter of secondary importance, particularly as in his very valuable pathological report Captain Evans gives his opinion that plague pneumonia is due to infection from the blood rather than from the air-passages—that is to say, that the pneumonia is simply the expression of a septicæmia. The main facts pointing to a case being plague pneumonia, in addition to its generally septic character, which has already been sufficiently described under general symptoms, are as follows. Cough may be very slight and occasional. The breathing, taking into consideration the high temperature, is little hurried or laboured, and the ordinary pneumonic disproportion of pulse and respiration rate is reversed. The pulse is the rapid feeble septic pulse already described, probably 120 per minute. The sputum like the cough, tends to be very scanty and occasionally so much so that in very many of my cases there was no opportunity of seeing it. As a rule it is clear and mucoid, very like bronchitic sputum. Occasionally it may be faintly muco purulent. Rusty sputum I have only seen once, and it was welcome as I had just shown the case to a medical sceptic who on the strength of a first expectoration, bronchitic in character, had declared the case to be simple bronchitis. The rusty sputum came only after forced coughing. Blood in the sputum I have seen twice. In one case there was a history of almost hæmorrhage from the lung. Prune-juice sputum I have never seen.

[5] Captain C. H. Evans, I.M.S., Plague Commissioners' Report, vol. i., p. 244.

Physical signs.—Very frequently on the first day or two of illness it will be found impossible to make out anything abnormal in the chest Then will be found probably in one or both apices a small patch some two inches in diameter with bronchial breathing and increased vocal resonance and a few fine moist râles Dulness on percussion, as a rule, is very faint, if made out at all. The rest of the lung will probably be normal, but an occasional râle or rhonchus may be made out All the signs given may be very faint and over a very small area, but if present at all, however faintly, they may be taken, as far as my experience goes, as almost inevitably indicating a fatal result. So often has it been only after repeated examinations that such a patch has been found, and so liable is it to be overlooked, that I am inclined to call any case pneumonia as soon as I find cough present and to assume that the patch has either been overlooked or else is too deep in the lung to cause definite physical signs The result of post-mortem examinations as recorded by Major Childe, Captain Evans, and others in their reports supports that view, patches of from the size of a walnut to that of a pea being described. Of course, at times the patches are widely distributed over the lungs and may form a consolidated mass over the greater part of one lobe giving clear physical signs, but in my experience this is not common. Other observers, while agreeing for the most part with my description, lay less stress on the paucity of physical signs and describe the sputum rather differently. Thus Major Lyons, I.M.S , says: "The expectoration is diagnostic from that of ordinary broncho-pneumonia, it being less viscid from the first, and early becomes profuse and watery and generally tinged with blood or reddish from admixture of blood."[6] Major Childe makes it "loose and free, coming up with the slightest cough, looking more like serum than mucus, and it was slightly pink, not rusty-yellow at all " "It is not always as described" ; it may be "much less profuse," "and in some cases the presence of blood is a marked feature." Captain Thompson makes it "seromucoid, scanty, and occasionally tinged with blood." Dr. McCabe Dallas describes it similarly. All, however, note the comparative absence of dyspnœa. I have described a form noted in the epidemic of 1899 where the general symptoms were very mild, rather bronchitic in character, and only the excessive pulse-rate and the unexpected fatal termination gave the clue, but in the epidemic of 1900 such cases were not common.[7] The duration of these cases may be up to 10 days.

Bacteriological examination—Major Childe states that cultures can always be obtained from the fluid from the trachea and bronchial tubes. Personally I have had little opportunity of testing this, as, in the words of Captain James, "none of us had time for laboratory or investigation work. The time of a plague medical officer is far too occupied for leisure for scientific research."[8] On the few occasions upon which I have tried to cultivate from sputum only mixed cultures from ordinary mouth organisms were recognisable.

THE SEPTIC TYPE.

This type of plague is best described as plague where neither glands, buboes, nor pneumonia can be detected Major Childe describes a definite condition of multiple affection of the glands, but those are more likely to be detected in the post-mortem room than at the bedside. Moreover, they are to be found along with typical buboes

THE INTESTINAL TYPE.

Less than 5 per cent of the investigated cases were of this type. They were generally registered as cholera, but the high fever and the bloody nature of the stools put this out of the question. Dr. E C Pettifor, my colleague, has seen a case with 30 motions a day and a bubo in addition. The diarrhœa in ordinary bubonic cases may be very marked In District 10 in the epidemic of 1896–97 in Bombay the proportion of this type is put down as 3 per cent[9] The stools are generally described as thin, yellow, and bad smelling. Major Gibbons, I M S., has described to me a case where the bowel on post-mortem examination was full of black blood It is a very severe and rapid type as a rule, thereby distinguishing it from typhoid fever or dysentery; in cholera one would have the coldness, collapse, and rice-water stools.

THE CEREBRAL TYPE.

I have called this cerebral in preference to meningeal, as in so many cases where the symptoms would have led to the expectation of finding at the post-mortem examination gross meningeal or cerebral lesions none have been present Sometimes, however, distinct signs of meningitis are present, according to Captain Thompson 0 66 per cent. He says: "The frequent presence of cerebral disturbance and the rarity of true meningeal inflammation would seem to prove that the symptoms depend on toxæmia."

THE CARBUNCULAR TYPE

This type of plague is rare. In the last epidemic I only saw one case of it and in the previous epidemic only three cases What struck me in most of those cases which I did see was the superficiality of the swelling and the fact that the induration was marginal rather than deep, also there were no deep excavating sloughs, but only a shallow widespread sloughing of the skin Dr. K. C. Bose, C.I E , has remarked the same thing. At the same time I have seen very deep excavation of the thigh in Calcutta and another huge excavation in the lumbar region in Poona Captain Evans got cultures from a carbuncle on the face, but does not describe it Our knowledge of this type is at present deficient, and our diagnosis must rest mainly on probability and the excessive gravity of the symptoms compared with the size of the carbuncle. One case of this type was seen by a number of medical men, the diagnosis of plague made by the district medical officer having been questioned. At least one of those gentlemen declared the man to be suffering from simple boil on the buttock, and all came to the conclusion that it was not plague. Nevertheless the man died within 24 hours.

DISEASES LIKELY TO BE CONFOUNDED WITH PLAGUE.

It must, in the first place, be remembered that there is hardly one of the specific fevers in which glandular swellings do not occasionally occur even if rarely and that in an epidemic of no matter what disease there is the liability to have abnormal and malignant cases of very short duration that approximate plague in general characters: for example, a case of measles with meningitis In such cases probability must be taken into account. I shall only mention those diseases which have actually been mistaken for plague in Calcutta or have at least caused difficulty

Puerperal fever—Plague in pregnant women almost invariably causes abortion or premature delivery. The point to be noted, then, in puerperal fever is whether the fever has come on before the onset of labour such a case must be looked upon as suspicious Plague under such conditions is very liable to be overlooked

Septicæmia—In septicæmia the diagnosis is bacteriological or by probability.

Pyæmia.—I recall a case where even at the post-mortem examination the diagnosis was not clear whether it was pyæmia or plague, incipient pus formation being evident in the gland substance of the mamma and about the glands of the neck. Cultures settled that it was plague Another case was diagnosed in hospital as pyæmia and sloughing of the scrotum, but I still maintain that it was plague for the following reason With the onset of fever came a right axillary bubo On the third day glands appeared in the left inguinal region and swelling of the left testicle By this time the axillary bubo had almost entirely subsided. This rapid subsidence I have seen more than once in cases of multiple bubo, but it is highly improbable that a pyæmic swelling in a case like this, which went on to a fatal termination, would thus resolve

Small pox—I have once diagnosed small-pox as plague and have twice seen it thus diagnosed. The advent of the eruption, of course, made the correct diagnosis clear.

Influenza.—The more malignant forms of influenza are extremely difficult to distinguish from plague without cultures for the leading characteristics of both diseases are the same. In both nervous disorders are predominant and in both the pneumonia is lobular and ill defined; sweats are highly characteristic of influenza, but may not infrequently be seen in plague.[10]

[8] Report of the Outbreak of Plague in the Jullunder and Hoshiapur Districts of the Punjab, 1897 98, p 147

[9] Gatacre's Report, p. 132.

Cerebro-spinal meningitis.—This, like the last-mentioned disease, I have also mistaken for plague. Meningeal symptoms are common in plague, but actual meningitis is rare. Hence one would not expect the extreme retraction of the head seen in cerebro-spinal meningitis. The symptoms also would not probably be relieved by lumbar puncture.[11]

Diphtheria and angina.—If the mouth can be opened there should be no difficulty. I saw a case on H.M.S. *Eclipse* of angina where the swelling of the submaxillary and cervical glands was so marked that the throat could not be examined, and owing to the severity of the general symptoms the case was at first looked upon as being very suspicious.

Erysipelas.—It must be remembered that diffuse cellulitis often complicates plague. I have seen the hand, the arm, and the shoulder affected. In another case when the left parotid bubo was subsiding there started from the right parotid a very œdematous cellulitis that passed over the vertex above, closed the right eye completely, and passed completely round the chin to the left side below.

Measles.—Twice I have seen morbilliform eruptions. They appeared about the tenth day when the patients were becoming convalescent. In one case this eruption became eventually hæmorrhagic.

Gonorrhœa.—As a rule there is little difficulty with this condition, but the following extraordinary case sent me completely astray. I went to examine a case reported by a very reliable practitioner as plague. To my surprise I found the patient sitting up in bed, talking freely and apparently free from fever. His appearance and symptoms seemed so incompatible with plague that when I had verified the presence of an inguinal bubo I naturally asked as to any history of gonorrhœa. The answer was to unwrap a penis swimming in pus. The case seemed clearly to be one of gonorrhœal bubo; either the medical officer had made a mistake or, what seemed more likely, the wrong patient had been shown me. However, within 24 hours of my visit the man died. On subsequent visits I got the true history of the case. The man after repeated contact with plague cases had suddenly got ill, a bubo developed, and for four days before my visit he had very high fever and delirium. On the morning of the day on which I saw him the temperature dropped for the first time and the symptoms subsided with the fever. In the evening the temperature again rose to 104° F., he became delirious, and on the next day he died. The urethral discharge was due to a chronic gleet which he had had for years and which got better and worse.

Syphilis.—Plague complicating syphilis is not uncommon. In Poona a man had been in the segregation camp for three or four days with a large hard sore on the penis and a couple of buboes, when suddenly he developed high fever and grave symptoms. I sent him to hospital as suffering from plague and the diagnosis was confirmed there. I have a history of an exactly similar case.

Mumps.—Occasionally mild cases with parotid swelling are presented for diagnosis, which may be very difficult to distinguish from mumps unless taken in connexion with previous and subsequent cases. The most marked case of this which I have had was that of a groom, aged 30 years, who was taken ill on Feb. 8th, 1900. Two days later he was seen walking about with two parotid buboes, a temperature of 101° F., and a pulse-rate of 120. He walked, talked, and moved about with the greatest freedom. On that same day he did his ordinary duty in riding horses. On the next day both glands had almost disappeared and with the exception of a little yellowish coating on the back of the tongue he was all right. There had previously been suspicious deaths in this collection of huts and in the next two months there were numerous cases. Most observers believe such cases to be plague, but it has yet to be proved.

Malaria.—This generally causes little difficulty. The edges of the tongue are not clean. In one case the patient had only four days previously recovered from an attack of malaria and was thin and anæmic. The temperature was 103° F., the pulse was 120, and the white tongue coating covered the tip and edges of that organ. No glands or pneumonia could be made out and the probable diagnosis seemed to be malaria; but as rats had been found dead in the house, and as his master wished it, he went to the hospital. He developed a bubo there.

Cerebral embolism and scrofulous glands.—These conditions have once caused difficulty.

Captain Thompson under "Diagnosis" notes many of the diseases given, and in addition mentions the following: epilepsy, cerebral apoplexy, uræmic coma, ulcer with sympathetic glands, diarrhœa, debility, marasmus, and phthisis. Major Lyons mentions relapsing fever, typhus fever, and alcoholic poisoning.

BACTERIOLOGICAL DIAGNOSIS.

Undoubtedly this is the great stand-by in diagnosis of plague, but this paper is already sufficiently long without taking it up. Moreover, in Calcutta the conditions of work have been such that we have had to work without the aid of either post-mortem examinations or cultures. The following practical points may, however, be mentioned. Puncture of a gland for diagnostic purposes is to be avoided unless in cases almost certainly fatal, for there is a risk that a simple case may be transformed into a septicæmic case. Cultures from the blood, the finger-tip, are not to be expected unless in virulent cases or shortly before death. Owing to the almost insuperable difficulty of separating the bacillus from mixed cultures there is a possibility of failure in an attempt to cultivate it from sputum, owing to the growth of ordinary mouth organisms. Major Lyons, however, says that "the presence in all cases of immense numbers of plague bacilli in the sputum, from which cultures can be obtained, renders the diagnosis certain." Judging from the results obtained in rats it is advisable that post-mortem cultures should be made, if possible, within 24 hours after death. The bacillus is not to be found in the pus of a bubo.

Calcutta.

LANDRY'S PARALYSIS.

BY P. RHYS GRIFFITHS, M.B., B.S. LOND.,
SURGEON TO THE CARDIFF INFIRMARY.

OPPORTUNITIES for observing the very interesting condition of acute ascending paralysis occur very rarely and it is for this reason that I wish to record the following case.

The patient was seen in consultation with his medical attendant, Dr. D. E. Powell of Cardiff. He was a tall, well-developed man, of dark complexion, 32 years of age. He was engaged as a railway guard. His wife told me that for a fortnight before the attack came on he had not been well. There were no special symptoms, but he complained of weakness and general malaise. He sent for his medical attendant on account of severe pains in the legs. At the time there was an epidemic of influenza and he was treated for this disease, but his condition gradually becoming worse he was seen by his medical attendant's partner on the evening before I visited him. They diagnosed Landry's paralysis and very properly expressed a grave prognosis.

When seen by me the patient was extremely ill and I was not able to make so thorough an examination as I should have desired. He was sitting propped up in bed supported by a friend and his face expressed considerable distress, but his mental functions were unimpaired. His breathing was very short and he told me that he was choking and that he was unable to swallow. He was given some milk and brandy, which he was quite unable to swallow.

On examination I found that his lower extremities were completely paralysed. His abdominal muscles were flabby and evidently paralysed. There was some slight movement of the chest, but the breathing was mainly diaphragmatic. There was well-marked paresis of the upper extremities and he was unable to control the movements of his head. There was no paralysis of the muscles of the face or of the muscles of the eye. His deglutition was seriously affected. Cutaneous sensibility, though not abolished, was notably blunted. His power of localising light tactile impressions was much impaired. No observation was made with regard to temperature or electrical skin reactions, nor was any attempt made to ascertain the electrical condition of his muscles. The sphincters were said not to be affected. The exact duration of the paralysis was uncertain, but as far as I could ascertain it must have been two or three days. It began in the legs and rapidly spread upwards. The pulse was rapid and feeble. His temperature had generally been about 100° F. He died a few hours after he was seen by me, the cause being stated to be asphyxia. I was unfortunately not able to secure a post-mortem examination.

In several of our text-books it is stated that Landry's paralysis is a rapid general motor paralysis, usually starting in the lower extremities without any very marked implication of the sensory apparatus. In looking up the notes of the historical case which occurred in June, 1859, upon which the definition of this disease is in the main based, it is stated that the senses of pain and temperature and the electrical sensibility were not affected, but that the muscular sense was lost in the feet and toes and tactile sensibility was diminished in the distal segments of the limbs and completely lost over the tips of the fingers. Landry states further that "sensibility and motility may be equally affected." Tactile sensibility was very markedly and very generally affected in my case.

I think it highly probable that the disease was the result of influenzal toxæmia. Dr Powell had no doubt that he was dealing with the ordinary form of influenza for some days antecedent to the onset of the paralysis.

Various other causes are given—e g., exposure to cold and alcoholic excesses. It has been attributed to the poisons of specific fevers, such as small-pox, typhoid, measles, diphtheria, syphilis, and septicæmia It occurs more often in men than in women, the ratio being three to one. It is a disease chiefly of adult life. The onset may be abrupt or it may be preceded by a variety of premonitory symptoms, mainly of a sensory character. Occasionally they may also be motor or the disease may be ushered in by a feeling of general malaise. The feature which overshadows everything else is the progressive diminution of muscular force, the finer movements disappearing first to be followed by the grosser. Although the feet are generally implicated first, yet this order may be varied by implication of the upper before the lower extremities. In about one-half of the cases the cranial nerves are affected. The nerves most often affected are those supplying the muscles of speech and deglutition. In some cases the soft palate alone is, or the soft palate and the epiglottis are, paralysed; in others—and this was a marked feature in my case—the pharynx and the œsophagus are also involved. Facial paralysis has been observed and also paralysis of the extrinsic and intrinsic muscles of the eye. Dr. Judson Bury states that the plantar and other superficial reflexes are probably lost. In my case there was no doubt that these had disappeared. The diaphragm is said to be generally involved before the intercostal muscles. I feel quite sure that this was not so in my case. The actual death-rate I do not know, but it is certainly very high. Dr. Judson Bury states that in 60 per cent. of the fatal cases death occurred before the tenth day; in 40 per cent. it occurred in two, three, or four weeks; occasionally it is fatal in two days

The pathology of this disease is at present obscure. In some cases no changes have been noted in the cord or nerves; in others the changes were those usually met with in myelitis; while in a further set neuritis of the peripheral nerves has been the main feature.

Cardiff.

ICHTHYOL AND ITS USES IN SOME SKIN DISEASES.

BY ALEXANDER BROWNLIE, M.D. EDIN.

IN publishing notes of some typical cases of eczema and acne treated with ichthyol I would point out that the results have been obtained in private practice, and not in hospitals, where patients have the advantage of trained nurses and resident physicians.

ECZEMA

Ichthyol, whether administered internally or applied externally, is, in my opinion, one of the most efficient agents in our hands for treating eczema in all its stages. The cases now quoted to show its value are not taken in any prescribed order but are selected at random from my notebook. The first case which I quote is the first in which I employed ichthyol, and as at that time my knowledge of the substance was limited my notes are naturally fuller of detail than in subsequent cases.

CASE 1.—The patient was a man, aged 33 years, married, with five children. When he was 16 years of age he had severe hæmorrhage during an attack of typhoid fever. He was of strumous constitution and had suffered from eczema for two years before seeing me in February, 1895. His face and neck were acutely eczematous, weeping, painful, and itchy. On the flexor aspects of his arms and thighs there was a drier form of eczema. His tongue was furred, he was constipated, and he had no appetite. I ordered light diet and gave internally a mixture containing nux vomica, liquor arsenicalis, and chiretta. The following ointment was applied externally twice daily: salicylic acid, five grains; ichthyol, 30 minims; resorcin, 20 grains; powdered boric acid, 30 grains; powdered starch, 60 grains; and vaseline to make up two ounces. On Feb. 17th there was no improvement and the itching was very bad; the ointment was also said to cause pain. I therefore stopped it and used the following: subnitrate of bismuth, two drachms; oxide of zinc, one drachm; ichthyol, 30 minims; and vaseline to make up two ounces. On the 21st there was still much itching. On the neck large brown epithelial scales were beginning to peel off. On the 26th, the arms and legs being dry, I prescribed 20 per cent. ichthyol paint in distilled water, which relieved the itching better than anything previously tried; 15 grains of trional were also given each night. On March 14th the neck and face showed some improvement, the exudation and pain being less. I now gave two and a half grains of ichthyol in a pill three times a day after food. On the 29th there was a distinct improvement. There was no more exudation and there were no papules on the face. For washing his face the patient used 10 per cent. ichthyol soap, and the ointment was changed to simple 4 per cent. ichthyol lanoline salve. By the middle of April the arms and legs were distinctly better, but the face and neck still showed some redness and a few papules. In May the patient was sent to Harrogate and he returned greatly improved in general health. The only symptoms of eczema now remaining were a slight scaliness of the neck and itching in parts which were quite healed. I therefore sent him to Dr. Allan Jamieson of Edinburgh, who prescribed a carbolic acid and spirit lotion with a weak ichthyol and resorcin ointment. The itching was not relieved at once but it gradually wore off. Any slight recurrence during the next two years was quickly subdued by 5 per cent. ichthyol salve. For the last three years he has had no more attacks.

CASE 2.—This patient was an unmarried man, 26 years of age, who was suffering from eczema of the leg, not varicose. Above the ankle there was a large red itchy patch, showing serous exudation. The treatment was commenced on Feb 21st, 1895. The part was directed not to be washed with soap but with oatmeal water. Ichthyol in five grain doses was given internally twice daily, and the following ointment was applied externally: ichthyol, 30 minims; subnitrate of bismuth, two drachms; oxide of zinc, one drachm; powdered starch, two drachms; and vaseline to make up two ounces. On March 1st the patient's condition was much improved. There was now no pain and no weeping, but the part was dry and scaly. A lotion containing 50 minims of ichthyol in an ounce of water was applied twice a day. On the 14th the skin was normal and the patient considered himself to be quite well. He has never been troubled since.

CASE 3.—This patient was a man, 68 years of age. He had a slight tendency to gout, but beyond this there was nothing particular either in his own history or in that of his family. The treatment was commenced on May 5th, 1899. There was eczema of the right leg, which from the knee to the toes was swollen to twice its usual size, pitted on pressure, was everywhere red, inflamed, and weeping, and in many places was covered with crusts, which on being detached left an exuding red surface On the right hand and arm there were small patches of dry and scaly eczema. Complete rest was ordered with elevation of the leg. A five-grain ichthyol pill was given thrice daily after food, and a mixture containing strychnine and digitalis to improve the circulation was ordered. The following ointment was applied twice a day: subnitrate of bismuth three drachms; ichthyol, 24 minims; and oxide of zinc ointment to make up two ounces On the 22nd the swelling, pain, and weeping were reduced, and large brown scales were detachable. The arm and hand were treated with 10 per cent. ichthyol lanolin salve. On June 10th the swelling was almost gone and the leg was in a dry and scaly condition, except at a small spot on the back. The following ointment was then applied: ichthyol, one drachm; ammoniated mercury, 10 grains; resorcin, 20 grains; vaseline, one ounce; and lanoline to make up two ounces. On the 19th the leg was normal in size and it was dry. The patient was now allowed to walk. On July 30th the leg was quite well. This was a bad case, which had already been under other treatment for six months. The constant rest was helpful, but the relief afforded by the action of the ichthyol on the dilated vessels was the direct means of cure.

CASE 4.—This patient was a married woman, 60 years of age, who had for years suffered from recurrent attacks of eczema. Any nervous excitement or worry brought on an attack. Both knees and wrists were scaly, red, and itchy, whilst the lower part of the abdomen and vulva and the upper part of the thigh were red and painful and exuded a copious serous discharge. The treatment was commenced on Oct. 30th, 1899. The abdomen being very painful I applied at first simply a dusting powder of starch and bismuth with a little boric acid. On Nov. 9th I prescribed 15 grains of ichthalbin thrice daily in cachets. On the 17th there were much less pain and exudation. I now ventured to apply 3 per cent ichthyol lanoline salve which answered admirably; the itching was relieved and the skin soon resumed a normal appearance. On the legs and arms the following ointment was used twice daily: ichthyol, one drachm; ammoniated mercury, 10 grains; oxide of zinc, two drachms; resorcin, 10 grains; vaseline, six drachms; and lanoline to make up two ounces. An improvement was manifest from the first, and recovery followed in six weeks.

In the acute cases no washing with soap was allowed, but with warm oatmeal water instead. When the parts were dry 10 per cent. ichthyol soap was used. No special diet was imposed. Ointments were not merely smeared over, but were gently rubbed in and the parts were covered with lint, linen, or silk, no cotton or flannel being allowed to touch the surface. In cases of eczema of the face I have also used with benefit zinc-ichthyol salve muslin, but it is rather difficult to keep applied.

ACNE.

Ichthyol is particularly beneficial in this disease, both in acne vulgaris and acne rosacea. In the former strong external applications can be borne, but in the latter much weaker strengths must be used. The best results are obtained when external and internal treatment are combined, and in some cases of acne rosacea in which the skin is too thin and irritable to bear even weak solutions the internal administration of ichthyol alone with steaming will suffice to effect a cure. My general plan of treatment is to begin with five grains of ichthyol thrice daily after food, increasing to 10 grains. Every night and morning the face is steamed for 15 minutes and then washed with ichthyol soap made into a lather and allowed to dry on, which is then gently washed off with water. After each washing, if it can be borne, ichthyol salve (often combined with ammoniated mercury) is applied. In acne vulgaris, after steaming strong sulphur and ichthyol soap is used, with brisk rubbing by means of a flesh-glove. The diet is regulated. Ichthyol itself relieves mild cases of constipation, but if it does not I give a compound pill of iridin and euonymin or podophyllin.

CASE 1.—This patient, a married woman, 46 years of age, had been treated for acne rosacea for six years. When she was first seen by me in February, 1897, her face was red all over and the smaller blood-vessels were very prominent. The nose, the brow, and the chin were covered with inflamed sebaceous glands, partly papular, others pustular. Her face was painful and she could not go out without a veil. She was placed on five grains of ichthyol thrice daily, and the following ointment was applied twice daily: ichthyol, 25 grains; ammoniated mercury, five grains; and vaseline and lanoline, of each half an ounce. Improvement was perceptible from the first and in a fortnight it was distinct. The amount of ichthyol was now doubled and extract of nux vomica was given before meals. In another month there were scarcely any inflamed glands and the redness was confined to a few dilated vessels on the cheeks. Two months later there were no traces of acne and the patient has remained free from it ever since. This case had resisted all remedies for six years; improvement commenced immediately that ichthyol was given, and to ichthyol I unhesitatingly give the credit of the cure. A similar condition existed in this patient's daughter, aged 24 years; it yielded to ichthyol in an equally satisfactory manner.

CASE 2.—This patient was a female, 17 years of age, who suffered from acne vulgaris. Her face was covered with inflamed sebaceous glands and "blackheads." Constipation was also complained of. Steaming, brisk rubbing with flesh-gloves, and the use of sulphur soap were prescribed. Internally saline purges were given. As this treatment did not do the good that I expected I ordered 10 per cent. ichthyol soap and the following ointment to be rubbed into the skin night and morning: ichthyol, 72 minims; resorcin, 10 grains; vaseline, two drachms: and lanoline to make up one ounce. Internally five grains of ichthyol were given thrice daily and on every second night a compound iridin pill. Improvement was gradual but sure and in three months the cure was complete.

OTHER APPLICATIONS OF ICHTHYOL.

I have also used ichthyol with success in many other diseases, such as endometritis, in which I have had some startling results. Although it does not come within the proper scope of this paper I should like to mention one case of endometritis which under the ordinary routine practice would have involved the scraping of the uterine mucous membrane, but which was cured by continued nightly applications of glycerine-ichthyol tampons in the proportion of two drachms of ichthyol to one ounce of glycerine. This patient had had two mucous polypi removed from the cervix without relieving the pain, and she was therefore very reluctant to undergo another operation. The ichthyol treatment was persisted in for five months, and ergot, nux vomica, and potassium chlorate were prescribed at the menstrual periods. The result has been highly satisfactory, as all pain and feeling of "bearing down" are gone and the patient feels quite well again. I had a similar case in an unmarried woman with equally good results.

Recently I have used strong solutions of ichthyol to paint over sprains. The swelling was quickly reduced in the few cases in which I have tried it.

CONCLUSIONS.

My experience has been that from 2 per cent. to 5 per cent. ichthyol applications are best in acute forms of inflamed skins and from 5 per cent. to 10 per cent strengths in more chronic, drier conditions. In acne vulgaris anything up to 25 per cent.—namely, between 10 per cent. and 25 per cent.—is useful. In all cases the internal administration of the drug is an assistance. I believe that ichthyol taken internally has a direct influence on the skin and is most probably excreted by it. Moreover, the taking of ichthyol internally increases weight, and this applies more particularly to weakly, strumous children.

The one disappointment which I must record is that itching is not relieved as quickly as one might expect, certainly not as quickly as the pain is relieved. Patients express gratitude for the feeling of comfort experienced, but the itching soon returns. The itchiness does indeed disappear after a time, but it is always the last symptom to go.

In prurigo and pruritus vulvæ or ani I have not found much benefit to result from the use of ichthyol, particularly in those cases where there is no known organic cause such as diabetes, ulcus cervicis, or anal fissure. I have tried ichthyol in 11 such cases and in only one have I had satisfactory results. This patient was a pregnant woman with pruritus vulvæ.

When prescribing ointments I always advise the patients to use their oldest under-linen as ichthyol has a staining effect, although it is stated that if quickly washed in warm water any clothing thus stained is made quite clean again.

Ichthyol, of course, is not applicable to every case of eczema or acne, neither do I claim for it a specific action, but it is undoubtedly a useful drug in these diseases.

Redcar.

FOURTEEN AND A HALF HOURS' ARTIFICIAL RESPIRATION IN A CHILD ONE WEEK OLD; RECOVERY.

BY GEORGE E. KEITH, M.B., C.M. EDIN.

TOWARDS the end of August I delivered a lady in the country of a healthy boy weighing six and a half pounds. The birth was premature, but only by three weeks. The child was well formed in every respect and, with the exception of a very long and tight foreskin, there was nothing to remark about him. As there was evidently much difficulty in passing water, the urine taking a long time to come and the child screaming and kicking, circumcision was advised as early as possible. This was agreed to, but, owing to the mother having a very severe bilious attack on the day after the confinement and as her milk did not agree with the infant, the operation was postponed from day to day. On the morning of August 27th, one week after birth, the operation was performed. The child did not breathe well under the chloroform and he lost more blood than is usual. He slept for some hours afterwards and awoke in the afternoon looking quite natural. He was then put to the breast, but did not seem to care to take much nourishment. He was quiet until 9 P.M., when he became very wide awake and screamed for two hours. There was no trouble with the urine and he had passed plenty since the morning. At 11 P.M. he became quiet and on being put to the breast took a little milk, but he did not seem to care to take much. He was now very sick and brought up seemingly all the milk that he had taken. Immediately afterwards he went to sleep. Up to 3 A M. the nurse had looked at him several times and each time she found him sleeping heavily. At 3.15 A.M the mother asked the nurse if the infant had not better be roused and put to the breast, and on the nurse picking him up she noticed that his breathing was laboured and that his face was cyanosed. She at once brought him to my room and on seeing him I thought that he must have had a convulsion, but whatever had happened he looked alarmingly ill. I sent her back to the mother's room telling her to give the baby some weak brandy and-water, and hurriedly putting on my clothes I went to the other room, where I found a still more serious state of things, as the breathing of the child stopped entirely a few seconds after I arrived. To all appearances the child was dead On listening to the chest I found the heart still beating, so I at once commenced artificial respiration. Within two or three minutes I was able to desist as the natural breathing was resumed, and after watching the child for ten minutes I returned to my room. In a few minutes I was again sent for, again to see an apparently dead child. Artificial respiration was re-commenced, and after 20 minutes the natural breathing was established, but only to cease in a very few minutes. The heart was now very rapid and the colour was, if anything, worse, and though I began artificial respiration again it was more from a sense of duty than from any expectation of bringing the child to life. Very soon after commencing the artificial respiration for the third time the heart seemed as if it were going to fail as the beats dropped from about 200 to well under 100 to the minute, the exact number being impossible to count as I could only listen with my ear to the chest very hurriedly. I think this slowing of the heart's action was due to performing the forced respirations too seldom to the minute, as on moistening the lips with a good deal of strong brandy-and-water and increasing the number of respirations to about 25 to the minute the heart regained its rapidity. After this I never slowed down to less than 20 to the minute. Hour after hour this monotonous business went on and hour after hour I became more and more convinced that it was all wasted labour and that in spite of all my endeavours the child would ultimately die The first gleam of hope came after it had seemed that all hope had gone, for by noon with every forced expiration and inspiration there came a most ominous creak, showing that the lungs were filling up with fluid and that if this went on increasing the end could not be far off. By 12 30 midday this sound had increased in the most alarming manner and more and more force was required to drive the air in and out of the lungs. The heart was again beginning to show signs that it was being asked to do more work than it was able, the sounds becoming weak and the beats irregular. As early in the morning as possible I had wired to London for cylinders of oxygen to be sent down by passenger train and most fortunately the first arrived just at this time. A slight stream of oxygen was at once directed against the child's nose and mouth, the end of the tube being held a few inches away. Within 15 minutes there was a decided change for the better; the colour of the face lost its earthy look, the moist sounds noticed with the forced respirations gradually died away, and the heart sounds increased in strength and regularity, but still there was no attempt at natural breathing. During all those hours I kept the child warm, as well as possible, by laying him on a blanket over a rubber hot-water bottle which was changed frequently and by covering the chest with a blanket, at least as much as was possible. For nourishment it was only possible to moisten the lips with brandy-and milk, as there was no attempt made to swallow and I was afraid of fluid going into the air-passages if put into the mouth in larger quantities. There was no further improvement until 3 30 P.M., more than 12 hours after the commencement of the illness, when a very feeble attempt at inspiration was noticed. This happened at first every minute, but the intervals got shorter and shorter until at 4 30 P M. the child was inspiring entirely. Still there had been no attempt made at expiration, but the difference which the last hour had made was so marked that I began to hope that there was a slight chance of saving the child's life. The normal expiration began to return about 5 P.M., and in exactly the same manner as the inspiration, and at 5 45 P M. I was able to cease all artificial means of inflating the lungs—exactly 14½ hours from the onset of the symptoms. By now the condition of the child was pitiable. The chest and the upper part of the abdomen resembled raw beef, though the skin was not broken, the arms were red, excoriated, and marked all over with angry lines from the violent use to which they had been put. He was quite unconscious, there was no pulse at the wrist, the heart beats were very rapid, and the breathing was of the most shallow description. The skin covering the anterior fontanelle was depressed and every now and again there was a peculiar contraction of the muscles of the lower jaw. From the commencement of the illness the pupils had been contracted, but not very markedly so, and this condition continued for some days In the afternoon, as I was getting exhausted from the prolonged manipulation required for the artificial respiration, and not knowing how long it would be necessary to continue it, I wired for assistance from town, and though this arrived too late to relieve me of the manipulation there was plenty of work to do in watching the child. After such a terrible experience I felt that a medical man must be in constant attendance on the child day and night About 10 P.M. the child became very cold and I had him wrapped up in cotton-wool. The oxygen was kept constantly playing on his face until midnight, when it was stopped for an hour and a half, but it had to be begun again as the child became very cyanosed, and as immediate benefit was at once noticed the administration did not again cease for many hours. After the normal breathing commenced again he was fed by a spoon with brandy-and water and milk-and water alternately, 20 drops of the former being given at a time, but as there was much difficulty in getting him to take the milk-and water and none in taking the brandy-and-water, the latter was alone given for the next 15 hours; it was given every hour. The breathing was so shallow all through the night that the closest attention was required to say whether the child was breathing or not. At 3 A M. the temperature was 103 6° F. This was the first time that it had been taken. One grain of antitoxin was given and this brought the temperature down two degrees in a couple of hours. About this time the child appeared to become conscious as he gave a few feeble little cries, the first sound he had made for many hours. The bowels were moved early on the morning of August 30th, and as the motions were most offensive and unhealthy one grain of grey powder was given The child remained much in this state all day. I had him put to the breast in the afternoon, but he could not get a proper hold of the nipple so we had to continue feeding him with the brandy-and-water. The temperature did not rise above 102° all day and the heart beats gradually slowed down to 170, and it was now possible to feel that there was a pulse at the wrist, though it was not strong enough to count the beats. The oxygen was still being continuously used As night came on the child did not seem so well; his face became pinched and white, the pulse could no longer be felt at the wrist, the heart beats increased in rate and decreased in strength, there was marked Cheyne-Stokes breathing, and the temperature rose in a most alarming manner. At 1 A M on August 31st the temperature had reached 105°. The child was sponged with tepid water and one grain of antitoxin was given. This quickly brought the temperature down, until at 4 A M. it was 103 8°, when another grain of antitoxin was administered. This had the desired effect, and by 6 A M the temperature had fallen to 101° and it never again rose above that point. Thinking that the oxygen might be helping to keep the temperature up its continuous administration was stopped and it was only given when it was thought necessary, judged of either by the colour or the breathing. By 9 A M. the child was much better. The pulse was quite regular and countable at the wrist, the colour was better, and the breathing, although still shallow, had quite lost its irregular nature. He seemed out of danger, but after the fright that he had given us I still considered it necessary to have him watched continuously by a medical man. He was now screaming incessantly and he seemed to have much colic. The motions remained very offensive, so he was given 10 drops of fluid magnesia every two hours. As he still did not seem to take the breast properly all idea of bringing him up in that manner was abandoned and it was arranged for the Walker-Gordon Company to send down a supply of their milk every day. After a restless morning he became quiet about 2 P.M. and dropped into a sleep. Soon after the breathing became more and more shallow and the face again became cyanosed, but on allowing the inhalation of oxygen for a few minutes the respirations quickly improved. This happened three or four times during the afternoon, but beyond giving oxygen nothing more seemed necessary until 4.30 P.M., when suddenly, without the slightest warning, and after one or two catches in his breathing the respirations stopped entirely. I immediately began artificial respiration and turned on the oxygen. Fortunately this attack only lasted a few minutes. After this, beyond the most constant care and watchfulness, there was no further anxiety, and the little patient is now an ordinary baby of the age of three months. Indeed, it would be impossible to tell from his looks and his general condition what an alarming and dangerous illness he has been through. The manipulation does not seem to have injured him in any way. It was simply marvellous to see how quickly the marks resulting from the prolonged movements disappeared from his chest, abdomen, and arms.

It is not possible for me to come to any definite conclusion as to the reason why the breathing ceased for so long, nor have any of my friends been able to give me a reasonable explanation. Probably it was caused by a combination of the chloroform, the shock, the hæmorrhage, and the disordered stomach, but what part each played in the pathological condition it is difficult to determine.

There were several astonishing features about the case. The amount of brandy which the child required was, for his age, enormous. A smaller amount than 20 drops every hour was tried and the same quantity at longer intervals, but the result under both conditions was the same—he at once seemed to lose ground. The brandy was never at any time thrown off by the lungs; at least it was never noticeable in the breath, so that it is probable that the child used it all up in the struggle which he made for his life. It is also wonderful that this small child, only a week old, was able to stand the manipulation. He was not spared in any way; the urgent thing was to get him to breathe and no thought was given as to how he would be affected if he recovered his breathing powers. It may seem strange that I could keep up artificial respiration for over 14 hours with only occasional breaks, when my nurse did it; but after a time the action became entirely mechanical, and though I was thankful to stop I was not so exhausted as might have been expected. It may be added that the nurse has worked for me for some years and that she was of the greatest possible assistance.

Charles-street, W.

CLINICAL NOTES ON THE RESULTS OF A PURE PROTEID FOOD IN FIFTY-FIVE CASES (VARIOUS DISEASES).

BY R. E. WILLIAMSON, M.B., C.M. EDIN.

AMONG the many foods on the market at the present time there is some difficulty for the busy general practitioner to make a selection of one useful for all-round purposes as an adjunct to ordinary dietaries in sickness and one at the same time within reach of all classes. There are many that have valuable qualities but there are few that do not possess some material drawback—e.g., some disagreeable taste or difficulty of preparation—or that the price does not make them prohibitive to one's poor brethren, so that when such a one is found, which on extended trial seems to answer and maintain its position, I feel it is sufficient apology for giving one's experience. Exact scientific experiment in semi-country practice is impossible, and these notes only pretend to be those of ordinary clinical observation.

I have used plasmon now in 55 cases in my own practice, and my friend and neighbour Mr. H. Hebblethwaite has used it in six cases, four of them of typhoid fever, one of severe anæmia, and one of obstinate and persistent vomiting, and he says that he has never had such a satisfactory diet for patients suffering from typhoid fever and that they did splendidly on it, that the recovery of the anæmic patient was most rapid, and also that in the patient suffering from vomiting it was the first food tolerated.

The cases in my own practice are as follows:—(1) acute gastritis, five cases, in one of which, complicated with cirrhosis of the liver, the patient had very severe hæmatemesis; (2) chronic gastro-intestinal catarrh, 12 cases, three of these patients after somewhat acute paroxysms had catarrhal jaundice; (3) gastric neurasthenia, five cases; (4) anæmia, nine cases; (5) erysipelas, one case; (6) phlebitis, one case; (7) puerperal septicæmia, one case; (8) influenza, five cases; (9) pleurisy, two cases; (10) operation for removal of tonsils and adenoids, four cases; (11) tuberculous diarrhœa, three cases; (12) acute diarrhœa (from errors of diet), three cases; (13) carcinoma of liver, one case; (14) diphtheria, one case; and (15) cardiac disease with gastric complications, two cases. I am not going to give a description of each case, but shall pick out cases which I think may serve as types of the efficiency of plasmon, and I may premise that it seems to be of the greatest use in diseases of the alimentary canal, acute febrile conditions (e.g., influenza, pleurisy, septicæmia, &c.), tuberculous and wasting diseases, and in one case I saw distinct temporary benefit in a case of carcinoma of the liver and a great relief of the painful gastric symptoms.

The first case in which I used plasmon was that of my wife who had been ill for three weeks, suffering from an attack of influenza complicated with gastro-duodenal catarrh and exhibiting some symptoms of a typhoid nature; she had a persistent rise of temperature, varying from 100° to 101° F. in the morning, rising usually in the afternoon to from 103° to 104°, and subsiding in the evening to about the morning temperature. She was most carefully dieted; peptonised milk and other peptonised foods, various special foods, and other preparations in turn were tried, but nothing seemed to agree—all caused nausea, flatulence, and general distress; and when a friend wrote to me and asked if I had tried plasmon, stating that he had derived much benefit from it personally, although I was thankful for the suggestion I fear that I was very sceptical as to the result. I gave it first dissolved in water and added to a little thin barley-water and only in small quantities, two or three teaspoonfuls at a time; this seemed to agree perfectly and so I increased the quantity. I then gave it in chicken-broth, then in milk, gradually increasing the amounts, all of which proved satisfactory. *Post hoc* or *propter hoc* the change was almost magical. The gastric symptoms subsided, the temperature gradually fell, and convalescence was rapid, and faith in the remedy is now so unbounded that she always keeps it in the house and if there are any symptoms of stomachic derangement she promptly goes back to it.

The next case I tried it in was that of sub acute chronic gastric catarrh in an old gentleman, age 75 years, suffering from cardiac dropsy and with whom the taking of even the lightest forms of food caused distressing heart storms, usually only relieved by vomiting; he was put upon the plasmon on Dec. 10th, 1899, and it was given in a similar manner to that employed in the former case. There was a speedy abatement of the gastric trouble, a temporary attempt at cardiac compensation, and considerable lessening of the dropsy, but this was only transient, and the patient died on Jan. 6th, 1900, from gradual cardiac failure, but without any further return of his gastric trouble.

Of the acute cases of gastritis, all of which were alcoholic, I will mention one only—that of a female, aged 34 years. I had attended her frequently for similar attacks and she had also a cirrhosed liver. On April 2nd I was called up early as the patient was vomiting large quantities of blood; this continued for some hours at intervals. For the next two days she was fed per rectum, then plasmon dissolved in water and sweetened with saccharin was given in small doses, and as it agreed with her a similar course was pursued to that described in the former cases, and in spite of the tremendous loss of blood which had occurred her convalescence was more rapid than on any previous occasion, and up to the present time she has better health than she has had for the last two years.

In anæmia I have been greatly struck by the action of plasmon. Two of the cases were very severe in character, extreme breathlessness on the slightest exertion, palpitation, tinnitus, and a syncopic tendency being present. The rapidity of the improvement in these cases under rest, iron, and plasmon dissolved in milk (one drachm in half a pint of milk three or four times a day) was simply marvellous when compared with other cases similarly treated, but without the plasmon.

The case of puerperal septicæmia was that of a woman who was confined of her second child on June 18th, 1900. On July 1st she had a rigor; her temperature rose to 104·5° F. during the next few days, and she had several rigors more or less severe. On the 6th she had a very severe rigor and was violently sick; her temperature at 10 A.M. was 105·2°. She was put upon plasmon which agreed perfectly with her, and in the afternoon she seemed greatly better and the temperature had fallen to 103°. On the next morning it was 99·4°; on the following day it was normal and her convalescence was uninterrupted. The probable cause of the septicæmia in this case was a block in a faulty drain and insanitary conditions arising therefrom, which had in the meantime been rectified.

A woman, aged 32 years, started with severe erysipelas of the head, the neck, and the chest on July 3rd, 1900. This was followed by a large abscess formation over the right infraclavicular region which extended half way down the sternum, which was opened and drained on the 15th. After this the temperature fell and the appetite improved. On the 18th she was very sick and complained that all things disagreed with her and the temperature rose again. On that day she was put on plasmon, which at once seemed to suit her, and there were no further drawbacks.

In the cases of tuberculous diarrhœa, all of which were unfortunately in an advanced stage, plasmon most distinctly gave great relief; the diarrhœa was greatly lessened, the temperature was kept much lower, and the abdominal pain and distension were relieved. That life was considerably prolonged those who saw the cases were convinced, and they could not help thinking that had it been used in the early stages the prognosis of the cases might have been hopeful.

In the cases of acute diarrhœa plasmon answered well. One of them was an old lady, aged 92 years, suffering from bronchitis at the time and whose case seemed hopeless. She was kept for several weeks upon it and is now as well as she has been for the last three years, getting up daily in her bedroom.

It seems particularly good in neurasthenic cases and builds up the nervous system. Two of the cases of gastric neurasthenia had been for years under treatment, one under my care for four years and the other for two years and prior to that constantly under the care of other medical men, and for some months now the patients have been off my list and have had no medicine at all.

Personally I have used plasmon considerably, chiefly in the form of the chocolate and the biscuits, which I carried the whole of last winter on hunting days, as did several hunting friends, also on long days' shooting on the moors in Scotland and fishing in Yorkshire; and I have always found that I could stand the longest day with less fatigue for the moment and less feeling of exhaustion afterwards than formerly. One hunting friend, who has also a pack of beagles which he hunts himself on foot, told me that he always carries the chocolate now and that constant consignments of the chocolate have been sent out to three of his brothers who are at present serving in South Africa.

When at Aldershot this Whitsuntide I thought it would be a good opportunity of trying its sustaining properties and I had some sent down for the officers' mess. On the unfortunate Monday which will always be remembered at Aldershot as "Black Monday" all our officers, 23 in number, carried three sticks of plasmon chocolate; none of us suffered the slightest either from the heat or from the fatigue, and although we had breakfast at 5.30 A.M. and did not mess until 8 P.M., one of the senior captains told me that, with the exception of the chocolate and a drink of lime-juice and soda, he had absolutely nothing between times, that he felt quite fresh, and had no feeling of exhaustion.

So far I have not found a single patient object to it and being practically tasteless it can be added to other foods without destroying their natural flavour, thus allowing it to be given without detection—a property of material advantage when one has to deal with faddy patients.

What has struck me most in using plasmon is the ease with which it is digested and the variety of media in which it can be used; preferably in my own practice I use milk, animal broths, or barley-water. The majority of patients like it and express a feeling of comfort and well-being after taking it, and their rapid gain of weight is most marked. One of our nurses at the workhouse who was run down and anæmic, taking nothing in addition to her ordinary diet but a full teaspoonful of plasmon dissolved in half a pint of milk twice daily, gained three pounds in weight in a fortnight.

Since compiling these notes I have seen Captain —, who has returned from South Africa, one of the three brothers previously alluded to; his statement as to the use of plasmon chocolate I give in his own words: "It was splendid stuff—quite the best thing we had out there. I sent home for some more."

Otley, Yorks.

ESTIMATION OF IRON IN ANIMAL ORGANS.

BY PERCY A. E. RICHARDS, F.I.C.,
ASSISTANT LECTURER ON CHEMISTRY AND PHYSICS, CHARING-CROSS HOSPITAL MEDICAL SCHOOL, AND PUBLIC ANALYST TO THE PARISH OF ST. MARTIN-IN-THE-FIELDS.

THE amount of iron in human viscera is often a matter of considerable importance to the pathologist, but although that metal can be easily and accurately estimated, when present in any distinct quantity, by ordinary gravimetric methods, yet in the particular cases under consideration such a process frequently fails to give concordant results. This is due primarily to the small proportion of iron usually found in animal organs and also indirectly to the insoluble phosphates that are invariably present. A gravimetric method necessitates careful elimination of these during the process of estimation and it also entails the employment of a large amount of the organ for each operation. With a view to meeting these objections as far as possible the following process has been devised and has given most satisfactory results in practice.

From 50 grammes to 100 grammes of the moist organ are weighed in a platinum dish and heated over a Bünsen burner until all moisture is driven off, the organic matter is burnt, and only a black, charred mass remains. This is carefully moistened throughout with strong nitric acid, avoiding a large excess, and is then incinerated gently to prevent loss during deflagration. The great bulk of the carbon may thus be removed, the mass being treated a second time with acid if required and again incinerated thoroughly. It is, perhaps, hardly necessary to point out that the nitric acid should be previously tested to ensure its freedom from iron. The metal is now left behind with the other mineral matter and a small amount of carbon. This is treated with pure hydrochloric acid, is allowed to stand for five minutes, and is then warmed and transferred to a beaker. The basin is washed out with warm hydrochloric acid, the washings are added to the bulk, and the whole is boiled after the addition of a few drops of strong nitric acid. This ensures thorough oxidation, and neglect of this precaution involves possible inaccuracy due to the presence of ferrous, with the bulk of ferric, iron. The solution after boiling is diluted with an equal volume of water and is filtered, the residue is washed with hot water, and the filtrate is made up to 50 or 100 cubic centimetres. This forms the stock solution and from it a measured portion (from one to 20 cubic centimetres, according to the strength of the solution) is taken with the pipette and is transferred to a Nessler glass. To this is added one cubic centimetre of a freshly-prepared solution of potassium ferrocyanide (1 per cent.) and the mixture is at once made up to 50 cubic centimetres. If precipitation occurs or if the colour is too intense the portion should be rejected and a smaller quantity of the stock solution taken. The colour so obtained is matched against that given by a known quantity of a standard iron solution and the weight of the metal is thence found by calculation. A suitable iron standard is one containing 0·1 gramme of metal per litre, each cubic centimetre being then equivalent to 0·0001 Fe. Such a standard is

best prepared by accurately weighing out 0·1 gramme of the purest "flower" wire, dissolving this in the minimum amount of hydrochloric acid, oxidising the hot solution with nitric acid, added drop by drop, boiling off the excess of the latter, and finally making up with distilled water to one litre.

If desired the estimation as detailed above may be repeated, using sulphocyanide of potash in place of ferrocyanide, the red ferric sulphocyanide being formed in place of the blue ferric ferrocyanide. In this case greater care must be taken to prevent the presence of much nitric acid, which itself gives a red colour with the sulphocyanide and would hopelessly vitiate the results.

Another matter of considerable practical importance is the accurate estimation of the moisture, as the results obtained above should be expressed in terms of dry viscera. Any attempt at removing the whole of the moisture from the weight necessary for the iron determination is both tedious and imperfect. It is therefore best to cut off a small piece of the organ at the time that a larger amount is taken, to place this in a separate dish, to divide it into small, thin slices with a sharp knife, to weigh, and to dry thoroughly in a water oven, and weigh again. The percentage of moisture can thus be accurately found.

The organs chiefly examined consisted of the liver, the kidney, and the spleen, and with all these the process has given good and concordant results.

MILLER HOSPITAL, GREENWICH.

A CASE OF PERFORATING GASTRIC ULCER.

(Under the care of the late Mr. T. MOORE.)

THE fact that there was a thick layer of lymph on the surface of the stomach, together with the escape of much gas on opening the peritoneal cavity, prove fairly conclusively that in this case a perforation must have occurred, though it is probable that very little extravasation took place, and that the opening was rapidly closed by effused lymph. For the notes of the case we are indebted to Mr. R. S. C. Edleston, late house surgeon.

A woman, aged 22 years, a general servant, was admitted into the Miller Hospital at 10 P.M. on Oct. 19th, 1899, with symptoms of perforation of gastric ulcer. Six months previously the patient was treated by Dr. W. Groome for anæmia and apparently completely recovered and returned to work. She admitted having been rather breathless on
exertion, but she had never suffered from pain after takicompare
food or at any time until the evening of Oct 18th early exploration
was suddenly seized with violent pain sequestrotomy. This, the
pain continued throughout the nise treatment of hip-joint disease,
following morning th A E. J. Barker, who in 1888 showed
tha and bread-ag could be obtained after aseptic exploration
of thdmoni by a sufficiently ample anterior incision to enable, as far as may be, the products of disease to be evacuated with the aid of a gouge and irrigation. The great value of this method is that it reveals the exact nature of the disease, the condition of the synovial membrane and bones, and especially the presence of sequestra. It is more successful if performed early and before matter has escaped from the joint cavity and burrowed in the planes of fascia. Occasionally at this stage, if deemed necessary, a formal excision may be performed, but usually judicious gouging will prove much less severe and quite radical enough. The anterior incision, although preferable, is not essential, but asepsis is. Of course such operations must be followed by prolonged rest. In fact, after the wound is healed, the cases are treated like those more favourable ones which are cured by rest alone. The best results are obtained where the disease is synovial.

gastric ulcer and it was decided to open the abdomen without delay.

An incision was made under chloroform from the ensiform cartilage to the umbilicus. On opening the abdominal cavity (which was reached with considerable difficulty owing to the distension and matting together of the tissues) gas escaped freely. A layer of organised lymph having been turned up the anterior surface of the stomach was exposed, and just below the lesser curvature midway between the cardiac and pyloric ends three elevated and dusky spots were seen lying close together, and each of about the size of a sixpenny-piece; the layer of lymph immediately covering them was almost as thick as the palm of the hand. There was no evidence of perforation, the peritoneal fluid, though plentiful, being quite clear. The stomach was firmly fixed by adhesions and consequently its under surface could not be examined. The abdominal cavity was thoroughly washed out with a weak solution of boric acid in boiled water and the layer of lymph was carefully replaced over the affected area. Owing to the peritoneal adhesions the whole length of the peritoneal wound could not be accurately united by continuous suture and several fine interrupted silk sutures had to be put in. The abdominal wall was united by stout salmon-gut sutures, no drainage-tube being used. The patient made an effort to vomit at the completion of the suturing of the abdominal wound.

On Oct. 20th no vomiting had occurred since the operation. The pulse was 98, the temperature was 101°, and the respirations were 34. One pint of water was given by the rectum; only teaspoonfuls of water were given by the mouth. On the 22nd four-ounce pancreatised nutrient enemata were given every four hours, and the rectum was washed out with one pint of warm water containing 20 grains of sodium bicarbonate half an hour before each nutrient enema. On the 23rd the patient complained of severe thirst, and milk and water, half an ounce of each, were given every three hours. On the 24th the milk and water were increased to two ounces every three hours. Nutrient enemata were given as before. The patient slept well and suffered no discomfort, but as the temperature was oscillating, though it was never high, the wound was dressed, and there was a slight purulent discharge from the suture wounds at the upper and lower end of the wound; the lowest suture was removed. On the 25th the diet was altered, two ounces of mutton-broth being given alternately with two ounces of milk and water every three hours. On the 28th the wound was dressed and a large quantity of purulent discharge occurred from both points above mentioned. The lower part of the wound was freely opened and a drainage-tube was put in, the wound being gently syringed out with boric lotion. On the 30th the wound was dressed twice daily. On Nov. 1st there was less discharge and the upper part of the wound was healed. The diet consisted of three ounces each of beef-tea or mutton-broth alternately with three ounces of milk and one ounce of lime-water. The enemata were discontinued. On the 5th the wound was firmly healed except where the tube was put in. The food was the same as on Nov. 1st, but was increased to six ounces at a time. On the 8th one drachm of virol was given three times a day after food. The food was the same as above but was increased to eight ounces every three hours
On the 10th two eggs daily were added to the diet, one
parts of the caseous liver tissue ding. On the 13th
areas a definite organism was found drainage-tube
low power of the microscope the same concentric arrangement of rings as the bodies found in actinomyces. With high magnification these rings were seen to be composed entirely of delicate threads of cocci presenting little or no dichotomy and far more delicate in size than true actinomyces. Dr. Habershon and Dr Hichens detailed some of the literature of anomalous cases of oösporon and bacillary forms of actinomycosis, and came to the conclusion that though the case presented clinical and pathological features closely simulating actinomycosis it must be regarded rather as a variety of streptothrix infection. Macroscopic and microscopic specimens from this case were exhibited, and a specimen of true actinomycosis of the liver was also shown by Dr. Habershon by way of contrast.—Professor JOHN MCFADYEAN congratulated Dr. Habershon and Dr. Hichens on the interest of the case. His first impression on looking at the microscopic specimens exhibited was one of surprise, because he had in his possession many specimens resembling these which he had always regarded as true actinomycosis

CASHEL UNION HOSPITAL.

A CASE OF TRAUMATIC RUPTURE OF THE GALL-BLADDER; PERITONITIS; LAPAROTOMY; RECOVERY.

(Under the care of Mr. T. LAFFAN.)

FROM *a priori* considerations it might have been expected that the presence of bile in the cavity of the peritoneum would have resulted in a severe inflammation of that membrane, but experience shows that healthy bile may be extravasated for days or even for weeks in the peritoneal cavity without exciting any great degree of peritonitis. Thiersch removed[1] over 40 pints of bile from the abdominal cavity and the patient recovered. It is essential, however, that the bile must be aseptic, therefore the history of survival for many days after rupture of one or other part of the biliary tract can only have occurred in cases where the rupture has resulted from traumatism, for in most of these the bile will have been normal. In cases where the rupture has followed the presence of a gall-stone, or an ulcer, or some other pathological condition, the bile is nearly always infected with micro-organisms, and in such cases peritonitis rapidly follows. That healthy bile when extravasated can be absorbed to some extent has been proved by the experiments of Schuppel and Bosbrom, but *this power of absorption is probably only limited*, and sooner or later peritonitis results which ultimately proves fatal. A specimen in the museum of St. Bartholomew's Hospital shows a rupture of the gall-bladder from traumatism in which death resulted from peritonitis five weeks after the bile was first extravasated. Since these cases of traumatic *rupture of the gall-bladder or bile-duct survive several days* or even longer it is obvious that surgical interference would be likely to be followed by success. The first recorded case of operation for rupture of a bile duct was under the care of Mr. W. H. Battle[2]; the operation was performed on the eighth day, but the boy died on the following day. A very similar case under the care of Mr. W. G. Spencer[3] was reported in which death resulted on the thirty-third day.

A married woman, aged 50 years, was trodden on by a cow while in the act of milking it. She felt something give way inside, and after suffering for some time from all the symptoms of acute inflammation was admitted to Cashel Union Hospital on Sept. 15th, 1898.

On admission the patient was in an alarming state, being almost moribund. She was deeply jaundiced and all the symptoms of peritonitis were present. The effusion was, however, circumscribed, presenting the appearance of a considerable *tumour in the epigastric and adjacent* regions. The patient was put under chloroform and with the assistance of Dr. T. O'Connell, Dr. G. Cook, and others laparotomy was performed. A large quantity of bile, pus, and some liquid fæcal matter were evacuated. The cavity was washed out with antiseptic solution, a drainage-tube was inserted, and the wound was sutured, with the exception of the opening for the tube. The patient was so weak and the parts being so matted as to require a regular dissection to unravel the point of rupture, it was deemed more prudent to make it an operation *de deux temps* if necessary. The necessity for a second operation, however, did not arise, as after an uneventful period the wound had been [illegible] glandular enlarge- ceased, and the [illegible] referred to the rarity of the tumour

Remarks [illegible] possible origin from fœtal rests in the deeper parts of the raphe of the tongue.

Dr. WILLIAM HUNTER narrated a case of Acute Yellow Atrophy occurring in a woman, aged 47 years, who was admitted into hospital with a history of two weeks' illness. On admission she was delirious and there was intense jaundice. She became comatose and died 24 hours later. It was thought to be a case of cirrhosis of the liver, but at the necropsy the liver showed the usual signs of acute yellow atrophy. It weighed only 30 ounces. There were purpuric hæmorrhages in the skin and hæmorrhages into the peritoneum and intestines. There was slight ascites, but there were no lesions in any other organs excepting the kidneys. On section the liver presented a deep orange-yellow colour. Microscopically, there were three different kinds of change to note. First, the deep red parts showed intense bacterial necrosis. Under a low power there appeared to be a fine-celled infiltration, but under a high power this cellular material was seen to consist of a necrosed disintegration of the liver cells. It was not atrophy but complete dissolution. Secondly, in the

tion of the cases, though many died from hectic fever and exhaustion after prolonged suppuration. The introduction of excision led to more rapid healing and was a great advance in *so far as it demonstrated that it was possible to remove* all the diseased tissue from the joint; but in many cases excision leaves a limb which is of no value to the patient, for it is not rarely quite incapable of sustaining any portion of the weight of the body. The present diminution in the frequency of excision is to be partly credited to this, and in part *to the fact that prolonged rest with or without less* drastic operative treatment in a large proportion of cases suffices to bring about recovery with a useful limb. Mr. Neve's cases recorded below demonstrate clearly the valuable results of early judicious treatment of disease of the hip.

CASE 1.—A child, aged eight years, was admitted into the Kashmir Mission Hospital on May 4th, 1896, suffering from hip-joint disease with dislocation backwards of the head of the femur. The joint was opened by a posterior incision three and a half inches long and some ounces of thin pus were evacuated. The acetabulum was filled by a globular mass of tuberculous synovial membrane of the size of a walnut. After this had been removed the joint was cleansed with the irrigation gouge and hot flushing, the dislocation was reduced, the cavity was dried, iodoform was introduced, and the wound was completely closed. On the 16th the wound was soundly healed. *On June 8th the patient was dismissed with instructions to continue rest.* The limb was in good position and the joint was moveable without pain.

Even where there is caries satisfactory results may be obtained by similar treatment.

CASE 2.—A boy, aged 14 years, was admitted into the Kashmir Mission Hospital with much tenderness and thickening of the hip, which was flexed and rigid. On July 23rd, 1896, Mr. Arthur Neve opened the joint by an anterior incision. The head of the bone had disappeared by absorption. The remaining carious surface having been gouged and the joint cavity having been cleansed and dried iodoform was inserted and the wound was closed. Union occurred by first intention. The limb was one and a half inches shorter than the other. The patient was discharged on August 20th.

Where, as sometimes happens, a sequestrum is lying loose in the joint *its removal by operation is especially indicated.*

CASE 3.—A little girl, aged six years, was admitted into the Kashmir Mission Hospital on April 28th, 1896, suffering from great pain in the hip. All the classical signs of disease of the joint were present and there was marked swelling behind the great trochanter with fluctuation. By a posterior incision about eight ounces of sero-purulent fluid were evacuated and a sequestrum was found consisting of the entire head of the femur. After the carious inner aspect of the neck had been dealt with by means of gouge forceps and the joint had been thoroughly cleansed and dried iodoform was inserted, and the wound *was completely closed.* This healed by first intention. Progress was uninterrupted and on May 15th the patient was allowed to go home.

Such cases demonstrate the great advantage of closing the wound and obtaining primary union. The real advance consists chiefly in earlier interference, more thorough removal *of diseased tissue, and the abolition of the drainage*-tube. The last is a mechanical irritant and is only too apt [illegible] the occurrence of sepsis, especially in little children [illegible] the dressings of the hip are exposed to great [illegible] If this be avoided, then excellent [illegible] with drainage.

Exhibiti[illegible] was admitted into th[illegible] 24th,

A CLINICAL meeting of this society [illegible] 1891, with a [illegible] Dr. J. DUNDAS GRANT, the President, being [illegible] chair.

Dr F. J. SMITH showed a case of Cirrhotic Kidney showing well-marked Albuminuric Retinitis. The patient was a labouring man, aged 40 years, who came under Dr. Smith's observation in March 1900 complaining of headache and shortness of breath. Inquiry revealed that there was also considerable amblyopia, and ophthalmoscopic examination at once showed very marked retinitis albuminurica. He was admitted into the London Hospital and improved with the rest in hospital without any special medicinal treatment, and was discharged at the end of May to the out-patient department. During the summer he complained principally of vomiting and of bad sight, with attacks of shortness of breath, and in October became so bad that Dr Smith again admitted him into the hospital. Dr. Smith remarked that the patient's symptoms were principally those of [illegible]

best prepared by accurately weighing out 0·1 gramme of the purest "flower" wire, dissolving this in the minimum amount of hydrochloric acid, oxidising the hot solution with nitric acid, added drop by drop, boiling off the excess of the latter, and finally making up with distilled water to one litre.

If desired the estimation as detailed above may be repeated, using sulphocyanide of potash in place of ferrocyanide, the red ferric sulphocyanide being formed in place of the blue ferric ferrocyanide. In this case greater care must be taken to prevent the presence of much nitric acid, which itself gives a red colour with the sulphocyanide and would hopelessly vitiate the results.

Another matter of considerable practical importance is the accurate estimation of the moisture, as the results obtained above should be expressed in terms of dry viscera. Any attempt at removing the whole of the moisture from the weight necessary for the iron determination is both tedious and imperfect. It is therefore best to cut off a small piece of the organ at the time that a larger amount is taken, to place this in a separate dish, to divide it into small, thin slices with a sharp knife, to weigh, and to dry thoroughly in a water oven, and weigh again. The percentage of moisture can thus be accurately found.

The organs chiefly examined consisted of the liver, the kidney, and the spleen, and with all these the process has given good and concordant results.

gastric ulcer and it was decided to open the abdomen without delay.

An incision was made under chloroform from the ensiform cartilage to the umbilicus. On opening the abdominal cavity (which was reached with considerable difficulty owing to the distension and matting together of the tissues) gas escaped freely. A layer of organised lymph having been turned up the anterior surface of the stomach was exposed, and just below the lesser curvature midway between the cardiac and pyloric ends three elevated and dusky spots were seen lying close together, and each of about the size of a sixpenny-piece; the layer of lymph immediately covering them was almost as thick as the palm of the hand. There was no evidence of perforation, the peritoneal fluid, though plentiful, being quite clear. The stomach was firmly fixed by adhesions and consequently its under surface could not be examined. The abdominal cavity was thoroughly washed out with a weak solution of boric acid in boiled water and the layer of lymph was carefully replaced over the affected area. Owing to the peritoneal adhesions the whole length of the peritoneal wound could not be accurately united by continuous suture and several fine interrupted silk sutures had to be put in. The abdominal wall was united by stout salmon-gut sutures, no drainage-tube being used. The patient made an effort to vomit at the completion of the suturing of the abdominal wound.

On Oct. 20th no vomiting had occurred since the operation. The pulse was 98, the temperature was 101°, and the respirations were 34. One pint of water was given by the rectum; only teaspoonfuls of water were given by the mouth. On the 22nd four-ounce pancreatised nutrient enemata were given every four hours, and the rectum was washed out with one pint of warm water containing 20 grains of sodium bicarbonate half an hour before each nutrient enema. On the 23rd the patient complained of severe thirst, and milk and water, half an ounce of each, were given every three hours. On the 24th the milk and water were increased to two ounces every three hours. Nutrient enemata were given as before. The patient slept well and suffered no discomfort, but as the temperature was oscillating, though it was never high, the wound was dressed, and there was a slight purulent discharge from the suture wounds at the upper and lower end of the wound; the lowest suture was removed. On the 25th the diet was altered, two ounces of mutton-broth being given alternately with two ounces of milk and water every three hours. On the 28th the wound was dressed and a large quantity of purulent discharge occurred from both points above mentioned. The lower part of the wound was freely opened and a drainage-tube was put in, the wound being gently syringed out with boric lotion. On the 30th the wound was dressed twice daily. On Nov. 1st there was less discharge and the upper part of the wound was healed. The diet consisted of three ounces each of beef-tea or mutton-broth alternately with three ounces of milk and one ounce of lime-water. The enemata were discontinued. MILLER HOSPITAL, GREENWICH.

A CASE OF PERFORATING GASTRIC ULCER.

(Under the care of the late Mr. T. MOORE.)

THE fact that there was a thick layer of lymph on the surface of the stomach, together with the escape of much gas on opening the peritoneal cavity, prove fairly conclusively that in this case a perforation must have occurred, though it is probable that very little extravasation took place, and that the opening was rapidly closed by effused lymph. For the notes of the case we are indebted to Mr. R. S. C. Edleston, late house surgeon.

A woman, aged 22 years, a general servant, was admitted into the Miller Hospital at 10 P.M. on Oct. 19th, 1899, with symptoms of perforation of gastric ulcer. Six months previously the patient was treated by Dr. W. Groome for anæmia and apparently completely recovered and returned to work. She admitted having been rather breathless on exertion, but she had never suffered from pain after takin compare
food or at any time until the evening of Oct. 18th early exploration
was suddenly seized with violent pain ir sequestrotomy. This, the
pain continued throughout the nigh treatment of hip-joint disease,
the following morning the r . A. E. J. Barker, who in 1888 showed

On the 22nd four-ounce pancreatised nutrient enemata were given every four hours, and the rectum was washed out with one pint of warm water containing 20 grains of sodium bicarbonate half an hour before each nutrient enema. On the 23rd the patient complained of severe thirst, and milk and water, half an ounce of each, were given every three hours. On the 24th the milk and water were increased to two ounces every three hours. Nutrient enemata were given as before. The patient slept well and suffered no discomfort, but as the temperature was oscillating, though it was never high, the wound was dressed, and there was a slight purulent discharge from the suture wounds at the upper and lower end of the wound; the lowest suture was removed. On the 25th the diet was altered, two ounces of mutton-broth being given alternately with two ounces of milk and water every three hours. On the 28th the wound was dressed and a large quantity of purulent discharge occurred from both points above mentioned. The lower part of the wound was freely opened and a drainage-tube was put in, the wound being gently syringed out with boric lotion. On the 30th the wound was dressed twice daily. On Nov. 1st there was less discharge and the upper part of the wound was healed. The diet consisted of three ounces each of beef-tea or mutton-broth alternately with three ounces of milk and one ounce of lime-water. The enemata were discontinued. On the 5th the wound was firmly healed except where the tube was put in. The food was the same as on Nov. 1st, but was increased to six ounces at a time. On the 8th one drachm of virol was given three times a day after food. The food was the same as above but was increased to eight ounces every three hours. On the 11th two eggs daily were added to the diet, one
parts of the caseous liver tissu dding. On the 13th
areas a definite organism was found pr rainage-tube

lesions such as those found on the husband's tongue. osis
result of treatment seemed, however, to confirm the syphilitic diagnosis.—Dr. W. H. KELSON instanced a case of syphilitic infection by means of the guillotine.

Dr. T. GLOVER LYON showed a case of Obscure Condition of the Chest in which the diagnosis was aided by means of the x rays. The patient was a boy, aged 15 years. There was no family history of phthisis. He had been quite well up to six months before when he had begun to suffer from general weakness, slight cough without expectoration, and some shortness of breath. On admission there was some emaciation present. The only abnormal chest sign was a very

CASHEL UNION HOSPITAL.

A CASE OF TRAUMATIC RUPTURE OF THE GALL-BLADDER; PERITONITIS; LAPAROTOMY; RECOVERY.

(Under the care of Mr. T. LAFFAN.)

FROM *a priori* considerations it might have been expected that the presence of bile in the cavity of the peritoneum would have resulted in a severe inflammation of that membrane, but experience shows that healthy bile may be extravasated for days or even for weeks in the peritoneal cavity without exciting any great degree of peritonitis. Thiersch removed[1] over 40 pints of bile from the abdominal cavity and the patient recovered. It is essential, however, that the bile must be aseptic, therefore the history of survival for many days after rupture of one or other part of the biliary tract can only have occurred in cases where the rupture has resulted from traumatism, for in most of these the bile will have been normal. In cases where the rupture has followed the presence of a gall-stone, or an ulcer, or some other pathological condition, the bile is nearly always infected with micro-organisms, and in such cases peritonitis rapidly follows. That healthy bile when extravasated can be absorbed to some extent has been proved by the experiments of Schuppel and Bosbrom, but this power of absorption is probably only limited, and sooner or later peritonitis results which ultimately proves fatal. A specimen in the museum of St. Bartholomew's Hospital shows a rupture of the gall-bladder from traumatism in which death resulted from peritonitis five weeks after the bile was first extravasated. Since these cases of traumatic rupture of the gall-bladder or bile-duct survive several days or even longer it is obvious that surgical interference would be likely to be followed by success. The first recorded case of operation for rupture of a bile-duct was under the care of Mr. W. H. Battle[2]; the operation was performed on the eighth day, but the boy died on the following day. A very similar case under the care of Mr. W. G. Spencer[3] was reported in which death resulted on the thirty-third day.

A married woman, aged 50 years, was trodden on by a cow while in the act of milking it. She felt something give way inside, and after suffering for some time from all the symptoms of acute inflammation was admitted to Cashel Union Hospital on Sept. 15th, 1898.

On admission the patient was in an alarming state, being almost moribund. She was deeply jaundiced and all the symptoms of peritonitis were present. The effusion was, however, circumscribed, presenting the appearance of a considerable tumour in the epigastric and adjacent regions. The patient was put under chloroform and with the assistance of Dr. T. O'Connell, Dr. G. Cook, and others laparotomy was performed. A large quantity of bile, pus, and some liquid fæcal matter were evacuated. The cavity was washed out with antiseptic solution, a drainage-tube was inserted, and the wound was sutured, with the exception of the opening for the tube. The patient was so weak and the parts being so matted as to require a regular dissection to unravel the point of rupture, it was deemed more prudent to make it an operation *de deux temps* if necessary. The necessity for a second operation, however, did not arise, as after an uneventful period the wound had been no glandular enlarge-ceased, and the pencer referred to the rarity of the tumour *Remarks* possible origin from fœtal rests in the deeper parts of the raphe of the tongue.

Dr. WILLIAM HUNTER narrated a case of Acute Yellow Atrophy occurring in a woman, aged 47 years, who was admitted into hospital with a history of two weeks' illness. On admission she was delirious and there was intense jaundice. She became comatose and died 24 hours later. It was thought to be a case of cirrhosis of the liver, but at the necropsy the liver showed [illegible] and Mr. [illegible]PARRAT.

Dr. T. R. BRADSHAW read a note on the preparation of Crystallised Albumins by G. Hopkins's Method and showed well-formed crystals obtained from the white of eggs and horse's serum. The latter were 0·5 millimetre in length and formed hexagonal prisms, terminated by a hexagonal pyramid at one end and a plane base at the other. With polarised light they were seen to be biaxial and with crossed Nicoll's prisms they showed straight extinction. Elementary analysis of the egg albumen crystals washed free from ammonium sulphate by means of a strong solution of sodium chloride and dried at 110° C. showed percentage of C. as 51·66 and of H. as 6·71.

tion of the cases, though many died from hectic fever and exhaustion after prolonged suppuration. The introduction of excision led to more rapid healing and was a great advance in so far as it demonstrated that it was possible to remove all the diseased tissue from the joint; but in many cases excision leaves a limb which is of no value to the patient, for it is not rarely quite incapable of sustaining any portion of the weight of the body. The present diminution in the frequency of excision is to be partly credited to this, and in part to the fact that prolonged rest with or without less drastic operative treatment in a large proportion of cases suffices to bring about recovery with a useful limb. Mr. Neve's cases recorded below demonstrate clearly the valuable results of early judicious treatment of disease of the hip.

CASE 1.—A child, aged eight years, was admitted into the Kashmir Mission Hospital on May 4th, 1896, suffering from hip-joint disease with dislocation backwards of the head of the femur. The joint was opened by a posterior incision three and a half inches long and some ounces of thin pus were evacuated. The acetabulum was filled by a globular mass of tuberculous synovial membrane of the size of a walnut. After this had been removed the joint was cleansed with the irrigation gouge and hot flushing, the dislocation was reduced, the cavity was dried, iodoform was introduced, and the wound was completely closed. On the 16th the wound was soundly healed. On June 8th the patient was dismissed with instructions to continue rest. The limb was in good position and the joint was moveable without pain.

Even where there is caries satisfactory results may be obtained by similar treatment.

CASE 2.—A boy, aged 14 years, was admitted into the Kashmir Mission Hospital with much tenderness and thickening of the hip, which was flexed and rigid. On July 23rd, 1896, Mr. Arthur Neve opened the joint by an anterior incision. The head of the bone had disappeared by absorption. The remaining carious surface having been gouged and the joint cavity having been cleansed and dried iodoform was inserted and the wound was closed. Union occurred by first intention. The limb was one and a half inches shorter than the other. The patient was discharged on August 20th.

Where, as sometimes happens, a sequestrum is lying loose in the joint its removal by operation is especially indicated.

CASE 3.—A little girl, aged six years, was admitted into the Kashmir Mission Hospital on April 28th, 1896, suffering from great pain in the hip. All the classical signs of disease of the joint were present and there was marked swelling behind the great trochanter with fluctuation. By a posterior incision about eight ounces of sero-purulent fluid were evacuated and a sequestrum was found consisting of the entire head of the femur. After the carious inner aspect of the neck had been dealt with by means of gouge forceps and the joint had been thoroughly cleansed and dried iodoform was inserted and the wound was completely closed. This healed by first intention. Progress was uninterrupted and on May 15th the patient was allowed to go home.

Such cases demonstrate the great advantage of closing the wound and obtaining primary union. The real advance consists chiefly in earlier interference, more thorough removal of diseased tissue, and the abolition of the drainage-tube. The last is a mechanical irritant and is only too apt [illegible] the occurrence of sepsis, especially in little children [illegible] ptic dressings of the hip are exposed to great [illegible] if this be avoided, then excellent [illegible] with drainage.

Exhibition [illegible] was admitted into the

A CLINICAL meeting of this society [illegible] 1891, with a lastly Dr. J. DUNDAS GRANT, the President, being [illegible] however,

Dr. F. J. SMITH showed a case of Cirrhosis [illegible] was in showing well-marked Albuminuric Retinitis. The p[illegible] a labouring man, aged 40 years, who came under the infirmary, [illegible] from the chest. The post-mortem examination showed very marked necrosis of the pleura at various parts and the pulsating air sac had been formed in the subcutaneous tissue of the chest wall. Dr. Harris referred to the great rarity of so-called pulsating empyema, and he had been unable to find any record of a pyo-pneumothorax where the air sac pulsated.

Mr. F. A. SOUTHAM made some remarks upon the conditions met with in a series of 50 cases of Recurrent Appendicitis treated by Operation; and a number of preparations were shown which illustrated the change produced in the appendix as the result of repeated attacks of inflammation.

Dr. A. HILL GRIFFITH mentioned two cases of Rodent had healed by first intention, but on August 5th a little clear serous discharge came away. This recurred at intervals until Sept 9th when the patient was allowed to go home. There was still well-marked thickening round the joint and the limb was flexed and rotated inwards. This case ran much the same course as if treatment by drainage had been intentionally employed.

Where, however, the wound becomes septic healing is apt to be greatly delayed. This is illustrated by the following case.

CASE 6.—A girl, aged three years, was admitted into the Kashmir Mission Hospital on June 16th, 1891, with well-marked hip joint disease associated with great pain. The joint was opened by a posterior incision some thin pus was evacuated, and a sequestrum of the size of a filbert was found consisting of part of the head of the femur. The joint was cleansed, iodoform glycerine emulsion was injected, and the wound was closed. On the 21st the joint appeared to be swollen and on the removal of stitches there was a discharge of pus. This continued until Sept. 16th, gradually diminishing in amount The progress of this case stands in marked contrast to that of Case 3, in which the pathological condition was almost identical.

Remarks by Dr. ERNEST NEVE.—That the tendency is strong for hip joint disease to terminate in a natural cure is shown by the large number of cases which recover under favourable conditions of rest Other cases, of a severer type, call for operative interference. Much confusion has been caused by statistical comparisons of the results of these two methods of treatment. The one class merges into the other, but typical cases are very different. Those lesions cured by rest alone include many early, subacute, mild, and otherwise favourable cases; while those treated by operation are apt to embrace cases of chronic, intractable, complicated, and progressively destructive disease which are also only too often associated with grave malposition. For it is in cases which, in spite of rest, are doing badly, that the surgeon is compelled to step in.

In the absence of treatment such cases usually go on from bad to worse. Sooner or later pent-up matter finds an outlet, sepsis ensues, and other evils follow in its train. Many patients come for the first time to the surgeon when this stage has been reached. I have notes of 10 cases, all of which had become septic when first seen; all had one or more sinuses and in most there were also extra-articular abscesses and the joint was more or less ankylosed in bad position. Five of these were treated by drainage alone and in five the head of the femur was also excised. Of those treated by drainage, one patient left the hospital after 48 days not improved, the discharge still being copious. The other four cases improved under treatment, but in three of them the hip, which was contracted on admission, remained so and it was deemed inadvisable to rectify this by excision or section of the neck of the femur. One of the patients was 60 years of age and the disease had been going on since childhood; another patient, aged 30 years, had a similar history. In the five cases in which excision was performed two of the patients left, not improved, after two months' treatment. One patient was healed in 44 days with a straight limb and
very little shorteni as healed in 67 days with the
limb in good pos was dismissed on the fifty-
fifth day improved little dis
The results obtai on or

ce e
r

In progressive hip-joint disease, especially where tension and pain are on the increase, the case for early operation is very strong. Where asepsis is secured and the operative treatment is judicious and adequate, the immediate results may be ideal. The completion and permanence of the cure will, of course, depend upon the maintenance of rest for a sufficiently prolonged period, until, in fact, the tissues of the joint area are sufficiently consolidated to bear the weight and strain of the body without injury.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Pseudo-actinomycosis of the Liver.—Carcinoma commencing in Supernumerary Nipples.—Fibroma of the Tongue.—Acute Yellow Atrophy of the Liver.

A MEETING of this society was held on Nov. 20th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Dr. S. H. HABERSHON and Dr. P. S. HICHENS communicated a paper on a case of Pseudo-actinomycosis of the Liver occurring in a lad, aged 17 years, admitted into Brompton Hospital in November, 1897. The symptoms on admission were those of cough with a little expectoration and pain in the right side of the chest. The liver was found to be enlarged. The physical signs observed were those of consolidation or condensation of the base of the right lung. No tubercle bacilli were found. The temperature remained at from 101° to 102° F. with some fluctuations. In December the boy coughed up a collar stud and this was followed by an improvement in the physical condition though not in the pulmonary physical signs. An exploratory puncture was made at the right base without results. The condition remained stationary for some time, but in February, 1898, an abscess formed over the sixth rib in the right nipple line which was incised by Mr. J. Rickman Godlee. The temperature began to assume a remittent type, and while suppuration continued the liver became more enlarged. More than one exploratory operation was made in the hope of finding a collection of pus, but without relieving the patient, who eventually became weaker and died. At the post-mortem examination the disease was found to consist of a collection of caseous masses in the liver, some of which near the upper surface of the right lobe had softened so as to form abscess cavities. The external operation wound communicated with the space between the liver and diaphragm, which was filled with caseous material. The right lung was condensed at the base and collapsed, evidently from old obstruction of the bronchi. The pus from the hepatic abscesses was found to contain pale-yellow or cream-coloured granules differing in colour, but of the same size as actinomycotic bodies, and on preparing cover-slips and stains with Weigert's modification of Gram's solution a fine mycelium was found, more delicate than that of true actinomyces and composed largely of strings of cocci. A description was given by Dr. Habershon and Dr Hichens of the appearances of the various parts of the caseous liver tissue. In the central caseous areas a definite organism was found presenting under a low power of the microscope the same concentric arrangement of rings as the bodies found in actinomyces. With high magnification these rings were seen to be
omposed entirely of delicate threads of cocci presenting
tle or no dichotomy and far more delicate in size
true actinomyces. Dr. Habershon and Dr. Hichens

He was not quite clear as to the distinction between actinomycosis and pseudo-actinomycosis. Presence of these fine threads which tended to take on sporulation might be a *point of distinction, but* he was not quite satisfied on that point. In the absence of cultures it was difficult to decide. He did not feel sure that these specimens deserved the name of pseudo-actinomycosis.—Mr. S. G. SHATTOCK agreed with Professor McFadyean in thinking that one could not rightly draw any conclusion as to the nature of the organism without making cultures. *He would like to ask Dr. Habershon* why he thought that this case was one of primary disease of the liver? In cases of actinomycosis there was always some lesion of the intestine, and he suggested that there might have been a healed lesion in this case.—Mr. A. G. R. FOULERTON also thought that without making cultures it was difficult to *decide as to* whether this was actinomycosis or some other streptothrix organism. When stained most of these organisms resembled each other and chain sporulation was common to them all. He remarked that the streptothrix actinomycotica lately isolated from cases of human infection had been a strictly anaerobic organism, and *therefore he would not* have expected to get cultures unless they were grown anaerobically. He did not like the term "pseudo actinomycosis."—Dr. HABERSHON, in reply, said that he had brought the case forward because he wanted help in the identification of the organism. In the recorded cases so few of the organisms were illustrated that it was difficult *to identify them. The prefix "pseudo" was undoubtedly* a resource of those who felt uncertain about the actual nature of a certain lesion. He confessed that his case might be a *variety of true actinomycosis, but he wished to mention* that all the six cases which had occurred at the Brompton Hospital had presented different features, and it was *the absence of these in the present case* which had weighed with him most in regarding it as a pseudo-actinomycosis.

Mr. W. G. SPENCER narrated a case of Spheroidal-celled Carcinoma having the characters of a rodent ulcer growing from sweat glands arising in a so-called super*numerary nipple. The growth originated in* a pigmented mole on the outer part of the breast of a woman, aged 58 years, 18 months before removal. The primary growth consisted of spheroidal cells covered by an ulcerating surface, *resembling the type of rodent ulcer believed to arise in sweat* glands. Mr. Spencer pointed out the interest of the case in that *malignant disease commenced in one* mole, whilst another unaltered one showed a similar structure; the former representing the actual, and the latter the potential, origin of malignant disease from fœtal rests. Previously recorded cases were referred to.

Mr. SPENCER also narrated a case of Fibroma of the Tongue, the specimen being exhibited. The growth previously to removal occupied the anterior fourth of a tongue, and it proved on microscopical examination to be composed of pure fibrous tissue. The patient was a man, aged 68 years. He had noticed the tumour for five weeks and it had continued to grow in spite of the administration of iodide. It formed a hard white tumour embedded in the muscular substance of the tongue, projecting a little from the under surface and being about three-quarters of an inch in diameter. It was well defined but not separated from the muscular substance by a capsule. It was taken to be an ordinary epithelioma before removal, but there had been no glandular enlargement. Mr. Spencer *referred to the rarity of the* tumour and its possible origin from fœtal rests in the deeper parts of the raphe of the tongue.

Dr. WILLIAM HUNTER narrated a case of Acute Yellow Atrophy occurring in a woman, aged 47 years, who was admitted into hospital with a history of two weeks' illness. On admission she was delirious and there was intense jaundice. She became comatose and died 24 hours later. It was thought to be a case of cirrhosis of the liver, but at the necropsy the liver showed [illegible] and Mr. [illegible]

Dr. T. R. BRADSHAW read a note on the preparation of Crystallised Albumins by G. Hopkins's Method and showed well-formed crystals obtained from the white of eggs and horse's serum. The latter were 0·5 millimetre in length and formed hexagonal prisms, terminated by a hexagonal pyramid at one end and a plane base at the other. With polarised light they were seen to be biaxial and with crossed Nicoll's prisms they showed straight extinction. yellow portions there were *fatty* degeneration and infiltration of the liver cells. Thirdly, here and there there was an inflammatory infiltration of certain parts, of a semi-necrotic character, representing the inflammatory reaction around the necrosed areas. As regards the bile ducts the larger ones were quite patent, but the smaller hepatic ducts were blocked with desquamating epithelium. Cultures had been made *from* the liver, spleen, and gall-bladder. The spleen was sterile, but the gall-bladder and liver contained the bacillus coli. No other organisms were detected. Microscopical examination of the kidney showed that the renal epithelium was in a state of complete degeneration and necrosis, somewhat resembling the hepatic cells. Dr. Hunter had collected records of cases of the disease and found that the average of the first stage in which there was slight jaundice lasted between two or three weeks. In his case it had been two weeks. The second stage, consisting of delirium passing into coma, lasted on an average from two to three days. In his case it was 48 hours. Many of the cases had not been recognised until the necropsy. Turning to the nature of the change in the liver he regarded it essentially as an acute bacterial toxic necrosis. The nature of the organism was doubtful. It was doubtful whether it could be the bacillus coli. The jaundice was probably due to the blocking of the intra-hepatic ducts. He referred to a case of acute yellow atrophy occurring in a child, aged eight years, under the care of Dr. Dawson Williams, who died after an illness of three or four weeks.—*Dr. H. MORLEY FLETCHER referred to the question whether* the changes of acute yellow atrophy occurred in a liver previously healthy or a liver which had already undergone some pathological *change. He* thought that in the specimens that were shown there was evidence of some antecedent fibrosis. He had had the opportunity *of seeing the case of the child to whom Dr. Hunter had* referred and of examining the liver after death. It showed distinct cellular and multi-lobular cirrhosis. Probably there was some infection on the top of this change. Two other cases to which he also referred presented some previous change in the liver. One was a man who was in the hospital *for some time with cardiac disease and the usual enlargement* of the liver. He was suddenly seized with symptoms of acute yellow atrophy and died. At the necropsy the cardiac liver was confirmed with the acute yellow atrophic changes supervening. Another case was that of a man in whom the changes of acute yellow atrophy were *found in the right lobe of the liver, to which they were* limited, the left lobe presenting old fibrotic changes.—Dr. A. G. AULD asked whether the nuclei were of inflammatory origin or whether they were the nuclei of the hepatic cells.—Dr. HUNTER, in reply, said that in the degenerated parts there were no nuclei at all left. *They were entirely destroyed.* In the inflammatory portions there were leucocytes and fibrous tissue-cells. Referring to the nomenclature he could not agree with the term "icterus gravis." It was a legitimate term to use but was open to this objection that it only connoted a severe jaundice, whereas there was a series of cases constituting a group of diseases, some of which died with large swollen livers, others with yellow atrophic livers, yet they all presented severe jaundice. The term "acute yellow atrophy" connoted all the distinctive features of the disease under notice.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on Oct. [illegible] Dr. J. DUNDAS GRANT, the President, being in the c[illegible]

Dr. F. J. SMITH showed a case of Cirrhot[illegible] showing well-marked *Albuminuric Retinitis.* The [illegible] a labouring man, aged 40 years, who came und[illegible] the infirmary, died when the p[illegible] was being [illegible] out from the chest. The post-mortem examination showed very marked necrosis of the pleura at various parts and the pulsating air sac had been formed in the subcutaneous tissue of the chest wall. Dr. Harris referred to the great rarity of so-called pulsating empyema, and he had been unable to find any record of a pyo-pneumothorax where the air sac pulsated.

Mr. F. A. SOUTHAM made some remarks upon the conditions met with in a series of 50 cases of Recurrent Appendicitis treated by Operation; and a number of preparations were shown which illustrated the change produced in the appendix as the result of repeated attacks of inflammation.

Dr. A. HILL GRIFFITH mentioned *two cases of Rodent*

Ulcer of the Eyelid and showed Microscopical Sections of the same.

Dr. C. POWELL WHITE showed two specimens of so-called Infective Sarcoma of the Vagina of Bitches. The specimens resembled those described by Washbourn and Bellingham Smith. In one of the bitches there was a growth in the mamma having the same structure as the growth in the vagina. Yet the animal recovered after both growths had been removed Both bitches were infected by the same dog, which also infected several other bitches and finally died as a result of the growths.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Aphasia.—Micro-organisms in Pus.—Heart Disease.

A MEETING of this section was held on Nov. 2nd, Professor A. C. O'SULLIVAN, the President, being in the chair.

Dr. H. T. BEWLEY exhibited the Brain from a case of Aphasia. The patient was a woman, aged 33 years, who in May, 1897, had an apoplectic seizure. When, after several days, consciousness returned it was found that there were (1) slight paralysis of the lower half of the right side of her face, which soon passed off, and (2) inability to speak This inability gradually lessened to some extent, but improvement soon ceased, and for the remainder of her life (she died from phthisis in February, 1898, nine months after the apoplectic attack) she was aphasic. The characters of her aphasia were as follows: 1. She was unable to recall the names of familiar objects shown to her, of flavours given her to taste, &c.; she, however, recognised their nature and understood their uses. 2 She understood simple sentences spoken to her—e g., the request, "Hold up your hand," but not more complicated or abstruse sentences 3. She could read written or printed words, but she did this slowly and with many mistakes, and the words when read did not bring any idea to her mind. She did not attempt to carry out any directions in writing, although she read the words. 4. She had very little power of voluntary speech; she usually communicated with the nurses by signs and was fully aware of the mistakes she made when trying to speak. She was never able to repeat a word deliberately, although she might have just used the word in a sentence. 5. She could copy words a little. 6 She could not write correctly, except her own name; if told to write some certain word she often wrote down some entirely different words. A hæmorrhage was found to have taken place in the neighbourhood of the left island of Reil, which had destroyed the grey matter of the convolutions of the insula and some of the adjacent white matter. A small cavity occupied the place of these convolutions, and around it was a quantity of yellowish substance containing many granules of hæmatoidin.—Dr. W. R DAWSON remarked that the island of Reil was fixed upon by Flechsig as his association-centre—a centre in connexion with that of hearing, of the motor organs of speech, and various other centres If this view were correct the physical element of speech would be damaged in the case of a lesion of this kind.

The PRESIDENT gave particulars of the Bacteriology of a case of Abscess involving the Frontal, Parietal, and Temporal Bones He isolated from the pus the streptococcus pyogenes and the staphylococcus pyogenes, albus and aureus. The streptococcus proved very virulent, one cubic centimetre of a broth culture injected intra-peritoneally into a rabbit and subcutaneously into a guinea-pig at about 2 P.M. causing death during the same night Neither variety of the staphylococcus produced any effect when inoculated into guinea-pigs or mice. —Professor E H BENNETT said that the patient was a child and the case was an illustration of what was not commonly seen—namely, a combination of tuberculosis with rickets Long ago, in 1858 or thereabouts, Sir William Jenner wrote the best account of these diatheses, as he called them, and one of the strong points of his description was the rarity of tuberculosis and rickets crossing each other. This child had rickets without doubt, his femora and shin bones bearing evidence of it. He was six or seven years old when tuberculosis supervened on the rickets and attacked him in many places. Over his left temporal fossa there was an abscess like the other tuberculous ones all over his body.—Professor E. J. MCWEENEY said that it was an interesting thing to find all the various pus cocci in the one specimen.

Dr. BEWLEY exhibited a Heart, the subject of Mitral Narrowing and Aortic Regurgitation. It was taken from the body of a female aged 20 years, who, while apparently in perfect health and without having complained of any symptom of disease, suddenly fell down dead while walking across a yard.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY —A general meeting of this society was held at 20, Hanover-square, W., on Oct. 31st, Dr. Douglas Kerr (Bath) being in the chair. The treasurer's balance-sheet for the year ending Sept. 30th, which showed that the financial position of the society was satisfactory, was presented and passed. Votes of thanks to the retiring President (Dr. Ivor Murray of Scarborough), the Council, and the officials of the society were passed.—Dr. Douglas Kerr then introduced the President-elect, Dr. Frederic Bagshawe (St Leonards). 26 new candidates were nominated and the President then gave an address on Some Points in the Development of Seaside Towns, an abstract of which follows. Dr. Bagshawe traced the early history and development of watering-places, specially dwelling upon the steps to be taken for the sanitation and water supply of such growing towns. Alluding first to the elementary methods adopted in early days and the dangers arising therefrom he showed what system of drainage had come to be employed in various seaside places, and pointed out that while nearly all discharged their sewage into the sea some had direct outfalls and some intercepting drains and tanks, making use of the ebb and flow of the tide to disperse the sewage at suitable times. He further showed that "the close aggregation of towns" around the coasts in certain parts must lead before long to considerable difficulty in the disposal of sewage; and that there was reason to fear lest the sewage discharged from one town might cause nuisance by being carried by the set of the tide and deposited along the shore of a neighbouring town. To remedy this, either some joint scheme must be hit upon by contiguous towns, by which this danger should be obviated, or some means must be adopted by which the solid parts of the sewage could be reduced and the effluent rendered innocuous. Of the various plans of sewage treatment hitherto in vogue a large number aimed at the precipitation of the solid matter in suspension by the addition of chemicals, the resultant sludge being then submitted to pressure and when dry disposed of as manure. This was, however, a costly and unsatisfactory process. Admirably adapted as sewage farms might be to many inland towns, they must remain an impossibility for most seaside resorts, owing to low levels and the want of available lands. The bacterial system seemed to have established itself firmly in the valleys of the Thames and the Exe and in other parts, and to be receiving recognition financially and otherwise from the Local Government Board. The great principle had been evolved that the rapid splitting up of the organic compounds in the sewage matters passing through the filters was due to the activity of the large number of micro organisms therein contained. The change was no longer accounted for as being a purely chemical or mechanical process. Bacteria worked their ends under two conditions—(1) in the closed or anaerobic beds, and (2) in the open or aerobic beds. The dangers arising from the discharge of sewage in the proximity of oyster beds had been demonstrated in the recent report of the Local Government Board the shell-fish therein gathered being capable of retaining the specific organisms of enteric fever in an active state for a month at a time. This might be counteracted by the use of the bacterial system, for it had been shown by Lawes and Andrewes that some liquefying organisms had a germicidal effect upon typhoid bacilli, so that their sojourn in a septic tank or their arrest in an anaerobic filter with such organisms diminished their chance of survival. This conclusion had been confirmed experimentally by Dr. R. Pickard of Exeter, who found that 90 per cent. of typhoid bacilli introduced into a septic tank were rapidly removed by bacterial agency. This system had been recently introduced at Morecambe in Lancashire and might prove very valuable where similar conditions prevailed or where seaside towns were closely aggregated. After alluding to the water-supply and other hygienic conditions of health resorts Dr. Bagshawe concluded by insisting on the importance of the presence of medical men on boards of health and sanitary committees, showing the power which they possessed of furthering the efforts of the medical officer of health in the cause of sanitation by the direct personal influence which they could bring to bear upon these bodies —Dr Robert Lee (London) proposed and Mr Ward Humphreys (London) seconded, a vote of thanks to Dr Bagshawe who briefly replied

Forfarshire Medical Association —This *society met in the University College Dundee, on Nov 1st,* Mr C S Young, Vice President, being in the chair —Professor J A C Kynoch showed a specimen of an Ovarian Tumour removed by operation per vaginam from a patient from whom he had removed a similar but larger tumour by the abdominal route He gave the reasons for his change in operation and discussed the relative merits of the two operations preferring the latter should it be at all possible —A number of pathological specimens were sent to the meeting by *Professor L R Sutherland* from the pathological museum, some of which had been presented by Sir William Gairdner —Dr A McGillivray read a paper on Advancement *versus* Tenotomy in the Surgical Treatment of Concomitant Strabismus and its Treatment by Optic and Orthoptic Means The merits of the two methods of surgical interference were discussed, convergent strabismus being taken as an example Advancement was shown to be more rational, being based on etiology and having for its object the strengthening of the disused and therefore weakened, external recti instead of the weakening of the unimpaired internal recti by tenotomy Both external recti should be advanced at the same time, as the condition was a bilateral one Cases were shown to demonstrate the above points —Professor A M Stalker gave an account of a case of Visceral Syphilis The patient a man, aged 47 years, was admitted into the hospital suffering from steady emaciation with a *history of hæmatemesis four months previously but without* the symptoms or physical signs of gastric disease There was no indication of syphilis He died and at the post-mortem examination the fatal lesion was found to be a stricture of the jejunum four feet from the pylorus due to a cicatrised ulcer In addition there was a healed ulcer of the stomach and extensive fibrosis of the heart associated with arterio-sclerosis and blockage of the coronary arteries —Dr C Kerr confirmed the diagnosis from his attendance and *treatment of the members of the same household —Dr* W E Foggie described the Nervous Sequelæ found in a man five months after he had been injured by a fall from a height of 40 feet which had apparently resulted in unconsciousness, retention of urine, and severe bruising but no evident fracture His present condition showed partial rectal and genital paralyses, symmetrical areas of thermoanæsthesia and analgesia over both heels enclosing much smaller areas of tactile anæsthesia, numbness and impaired sensation around the anus, increased *knee jerks, and pain in the bladder* and urethra as well as over each side of the small of the back These phenomena pointed to a hæmorrhage into the cord involving to some extent the sacral segments *from the* second to the fifth, and probably also their roots, unless the irritative phenomena above mentioned were secondary to the cystitis still present —Dr J Mackie Whyte asked if there was any relation between the sensory supply of the anus and that of the heels that would explain the above case, which did not seem in harmony with *Head's diagrams —Dr Foggie* in reply, acknowledged the difficulty and could only suggest that the cord had been injured in more than one place and at different levels —Dr Mackie Whyte gave an account of a case of a quarryman who had had during the last year and a half frequent attacks of dyspnœa with some cough and slight expectoration The physical signs were those of chronic pneumonia The patient died during an attack of dyspnœa These frequent attacks were characterised by their sudden cessation The post mortem examination showed the lungs to be those of a case of pneumokoniosis

British Laryngological, Rhinological, and Otological Association The annual general meeting of this society was held on Nov 9th Dr Barclay J Baron the President, being in the chair —The officers for the ensuing year were appointed Mr Mayo Collier being elected President —Mr Lennox Browne reported the case of a patient the subject of *Epithelioma of the Larynx* from which a (presumably) benign growth had been removed nine years previously Mr Browne remarked that although no microscopical examination had been made in the first instance it was not reasonable to suppose that recurrence would have been delayed so long had the case been one of squamous epithelioma as was revealed on the more recent occasion —Mr V H Wyatt Wingrave showed slides which illustrated the undoubtedly malignant nature of the removed tissue —Mr Lennox Browne also reported two cases of Epilepsy which had been benefited by removal, in the first case, of tonsils and adenoids from a child, aged five years, the subject of epilepsy in a grave form and with mental hebetude and in the second case by removal of adenoids from a female patient, aged 19 years, the subject of *petit mal.* It was a feature of note that in both cases bromide of potassium had been given in enormous doses without benefit before the operation, but it had proved most effective in very small doses (three grains) afterwards —Mr W J Chichele Nourse showed a middle aged man with Papillomatous Growths on the Left Vocal Cord —Mr E Dennis Vinrace showed a patient with extensive Ulceration of the Tongue —Dr J Dundas Grant considered the disease to be epithelioma engrafted upon tertiary syphilitic infiltration —Mr Mayo Collier said that the origin of the disease was no doubt syphilis; there were two ulcerating craters doubtless breaking down gummata —Mr Wyatt Wingrave Mr Lennox Browne, and Dr James Wilson (Liverpool) also spoke —Dr Dundas Grant read notes of a case of Nasal Synechia in a girl, aged 19 years There was no history of injury, but the prominent symptom pain across *the bridge of the nose had followed an attack* of influenza two years ago —Dr Dundas Grant also showed a case of Rapid Enlargement of the Cervical Glands in an elderly woman for which no peripheral cause was found The diagnosis lay rather between tubercle and some form of new growth —Mr Wyatt Wingrave showed a case of Congenital Syphilitic Ulceration of the Nose in a female, aged 20 years There was extensive scarring in the pharynx and widespread granulomatous ulceration in both nostrils *Marked improvement followed mercurial treatment —Dr* Dundas Grant said that he regarded the case as one of lupus —Dr F J Tresilian (Enfield) showed a case of Old-standing Tertiary Syphilis of the Nose, Pharynx, and Larynx in a man aged 40 years The larynx showed relics of extensive disease and there was a subglottic stenosis in the upper part of the trachea —Dr Tresilian also showed a girl aged 16 years, with a large new Growth in the Right Lobe of the Thyroid Gland and Abductor Paralysis of the Right Vocal Cord due to pressure on the recurrent *laryngeal* nerves —Mr *Dennis* Vinrace showed a case of Cleft Palate —Dr W H Kelson showed a man, aged 30 years with well marked Exostoses in both External Auditory Meatus —The newly elected President (Mr Mayo Collier) having taken the chair then delivered an address upon Mouth breathing and its Relation to Diseases of the Throat, Ear Nose, and Accessory Cavities This address will be found at page 1478

Society of Anæsthetists —An ordinary meeting of this society was held on Nov 2nd Dr J F W Silk the President, being in the chair —Mr Carter Braine communicated the particulars of a case in which Alarming Symptoms ensued when the patient was placed in the Trendelenburg Position The patient was a thin, feeble woman 28 years of age Anæsthesia was induced with gas and ether and the patient was placed in the Trendelenburg position After the incision in the abdominal wall had been *made chloroform was used instead of ether Mucus collected* with great rapidity in the pharynx, the breathing became laboured and there was marked cyanosis The symptoms were relieved when the patient was restored to the horizontal position but they immediately appeared again when the Trendelenburg position was used —*Dr Dudley Buxton* thought that the condition could be ascribed to some vaso-motor idiosyncrasy on the part of the patient —Mr A E Francis of University College read the notes of a case in which *the administration of Nitrous* Oxide *to a girl 10 years of age gave rise to* slow, shallow respirations great lividity, and enormous venous distension the heart on auscultation and percussion being found to be distinctly distended and a systolic murmur being heard over the displaced apex Both before and after the administration the heart was of normal size and there was no abnormal murmur The recovery was good and on a subsequent occasion when chloroform was used no trouble *followed —Mr H C Crouch, Dr R J Probyn* Williams Dr Dudley Buxton and Mr J K Foller discussed the case —Mr Francis replied —Dr G B Flux described a Valveless Stopcock for the administration of Nitrous Oxide by the Open System The instrument consisted practically of two tubes one rotating within the other, so as to open or to close the opening into the gas-bag. The inner tube was bevelled off so as to form an inclined plane by means of which the gas was directed into the face-piece, and there was always a large air-opening, the weight of the gas being relied upon to prevent undue admixture with air.—Dr. Probyn-Williams, Dr. H. Low, and the President took part in the discussion and Dr. Flux replied.—A communication from Mr. W. G. Copestake of Derby was read commenting on two recent deaths under chloroform.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society held on Nov. 7th a presidential address on Modern Sanitation was delivered by Mr. G. B. Wray, the President.—After referring to the sanitary enactments of the last 25 years and the difficulties experienced in getting rural district councils to adopt any of them he advocated the establishment of a Board of Health (detached from any connexion with Poor-law administration) to administer a new consolidated and amended Public Health Act, together with the Factory, Workshop, and Burial Ground Departments of the Home Office, and the Veterinary Department of the Privy Council, with an efficient staff of experts to act as inspectors, part of whose duty should be periodically to visit and to report on the sanitary condition of every district in the country. He also recommended the appointment of whole-time medical officers of health for every county, an increase in the powers of county councils, and the formation of combined districts for sanitary administration. After a lengthy description of experiments which he had been carrying out on the biological treatment of sewage, Mr. Wray laid special stress on the work done by the macroscopic agents of nature, such as worms and flies, and he urged a more vigorous enforcement of the Rivers Pollution Act to reclaim our dykes and streams and rivers from the opprobrium of being looked upon as open sewers. Attention was then drawn to the unsatisfactory condition of the houses of the working-classes and the many difficulties in the way of abating nuisances from overcrowding in rural districts, both of which were strong factors in fostering and propagating tuberculous diseases. A short allusion was made to the means which were being, and which might be, taken for the suppression and prevention of these diseases, and credit was given to the authorities who had done good work in this connexion by the registration and inspection of slaughter-houses, the inspection of meat, and the adoption and enforcement of regulations under the Dairies, Cowsheds, and Milkshops Orders.—A hearty and unanimous vote of thanks, which was proposed by Dr. H. Handford, seconded by Mr. T. Davies Pryce, and supported by Dr. W. B. Ransom, was accorded to Mr. Wray for his able and interesting address.

MANCHESTER THERAPEUTICAL SOCIETY.—The annual meeting of this society was held in Owens College on Nov. 7th. The following gentlemen were elected to be the officers for the session 1900–1901:—President: Professor J. Dreschfeld. Vice-Presidents: Professor Dixon Mann and Dr. A. T. Wilkinson. Honorary Treasurer: Dr. R. T. Williamson. Honorary Secretary: Dr. R. B. Wild. Committee: Dr. A. Brown, Dr. F. J. H. Coutts, Dr T. N. Kelynack, Dr. E. Vipont Brown, Dr. J. S. Bury, and Dr. E. S. Reynolds.—The President, after referring in feeling terms to the loss which the society had sustained in the death of Professor D. J. Leech—who, though already showing signs of his fatal illness, gave a communication on Saline Baths at the last meeting—delivered an address on Rectal Feeding. He stated that rectal feeding was an important and useful addition to the methods of treating disease, but in many cases it was ordered without careful thought and without proper directions to the nurse as to the quantity and kind of food to be thus administered. A sufficient amount of food to keep up the body-weight might not be given, but nutrient enemeta might aid by diminishing the rapid decrease of body-weight. The capacity of different parts of the bowel for the digestion and absorption of the different elements of food was then considered, and reference was made to the varying views which had been expressed on some of these points. He then gave details of the methods of compounding various nutritive enemata which had been found useful by clinicians, and spoke of his experience in their use. Next came the question of the indications for the employment of rectal feeding and then an exhaustive list of the conditions demanding this treatment either alone or supplementary to feeding by the mouth was brought forward.—Professor DIXON MANN pointed out that though egg albumen was absorbed from the rectum, albuminuria was sometimes found to occur, which would indicate that the albumen had not been retained by the tissues. Bacterial decomposition of nutrient enemata sometimes took place, as was shown by the presence of indican in the urine.—Dr. Bury, Dr. A. Hopkinson, and Dr. Wild also spoke.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The second meeting of the session of this society was held on Nov. 14th, Dr. D. S. Davies being in the chair. Before commencing the business of the evening the President in feeling terms referred to the death of a Past-President of the society—namely, Mr. S. H. Swayne, who had at all times been a most regular member.—Dr. J. Michell Clarke showed: (1) A case of Tumour in the Inter-peduncular Space; (2) a case of Tumour in the Motor Area of the Brain; (3) a case of Tumour of the Brain in a boy, aged eight years; and (4) a case of Progressive Muscular Atrophy commencing in the Shoulder Muscles.—Dr. E. H. E. Stack commented on the case of the cerebral tumour in the boy.—Mr. C. A. Morton showed: (1) A case of Diffuse Overgrowth of the Tissues of the Thigh; (2) a case of Congenital Varix of One Lower Limb, the Perineum, and the Penis; and (3) a case of Congenital Dislocation of the Hip, with Skiagram —Dr. A. Ogilvy showed patients with Congenital Anomalies of the Eyes.—Dr. T. Fisher showed a patient with Congenital Stenosis of the Pulmonary Artery, and Specimens of the Aorta and Pulmonary Artery arising from the Right Ventricle, and of the Aorta arising from the Right Ventricle, and the Pulmonary Artery from the Left Ventricle.—Dr. James Swain showed two sets of Multiple Calculi which he had removed by suprapubic cystotomy, and a Columnar Epithelioma removed by Colectomy, all from aged patients.—Mr. Morton, Mr J. Ewens, and Dr. Stack spoke on the subject.—Dr. A. B. Prowse showed a specimen of Cardiac Embolism.—Mr. G. Munro Smith showed a skiagram of a case of Stave of the Thumb, and a specimen from a child in which death was caused by the Impaction of a Piece of Walnut in the Larynx.—Dr. E. W. H. Groves read a paper on Eclampsia.—Dr. Aust Lawrence and Dr. W. C. Swayne discussed the paper —The reading of Mr. W. Roger Williams's paper on Medical Science in the Nineteenth Century, and of Mr. Paul Bush's paper on Hospital Treatment during the War in South Africa was postponed.—Mr. Paul Bush showed upwards of 200 lantern slides illustrating scenes during the Boer War.

BOURNEMOUTH MEDICAL SOCIETY.—The annual meeting of this society was held on Oct. 26th in the Hôtel Métropole, Dr. James Davison, the President, being in the chair.—The President referred to the loss which the society had sustained by the death of Dr. D. C. Embleton, a former President of the society, and he proposed, and the society passed, a vote of condolence with Mrs. Embleton and the family.—The report and financial statement for the year 1899–1900 were considered and adopted.—The President thanked the members of the society for the cordial support which they had given him during his year of office and he then introduced Dr. Arthur Ransome, F.R.S., the President-elect.—Dr. Ransome thanked the members for electing him as President and said that he would do whatever he could for the welfare of the society. He then proposed a very hearty vote of thanks to the retiring President for the way in which he had discharged his duties.—This was carried by acclamation.—On the nomination of the outgoing committee Mr. A. H. Vernon, Dr. D. M. Ross, and Dr. W. H. L. Marriner were elected treasurer, secretary, and librarian respectively.—The following members were elected on the committee for the year 1900–1901:—Dr. A. C. Coles, Dr. James Davison, Mr. T. Fred. Gardner, Dr. Marriner, and Mr. J. R. Philpots.—The business of the meeting having concluded 35 members and six visitors dined together. It was mentioned by one of the founders of the society that this meeting was the silver jubilee of the society, which was founded in 1875 and, therefore, a notable occasion.

WATER SUPPLY OF WELLS.—At a meeting held at Wells, Somerset, on Nov. 13th, under the presidency of the Mayor, it was resolved that it was expedient for the city council to acquire the undertaking of the Wells Water Company. It was stated that the water company had not kept their promise of giving a better supply and that the medical officer of health had also complained of the existing state of affairs.

Reviews and Notices of Books.

Occasional Lectures on the Practice of Medicine By W B CHEADLE, M D Cantab., F R C P Lond, Senior Physician to St Mary's Hospital, and Lecturer on Medicine in St Mary's Hospital Medical School, Consulting Physician to the Hospital for Sick Children, Great Ormond street, London · Smith, Elder, and Co 1900 Pp 324 Price 7s 6d

THIS volume consists of lectures addressed chiefly to the students of St Mary's Hospital Medical School, to which are appended Dr Cheadle's well known Harveian Lectures on the Rheumatism of Childhood which have been "revised and corrected up to-date" "These lectures were designed," says the author in his preface, "for the assistance of students in the everyday work of their profession by directing attention to some common errors in medical practice and by setting forth the importance of certain points in relation to the diagnosis and treatment of disease which are not dealt with in detail in the text books, are rarely treated adequately in clinical teaching, and which are therefore apt to be neglected or overlooked in actual practice" Dr Cheadle has succeeded admirably in his task. Each lecture is replete with information and contains numerous valuable hints, the result of prolonged experience and careful observation

The first lecture is entitled "The Use and Abuse of Tonics" The subject is certainly one which merits attention as numerous fallacies are prevalent with regard to it The laity are strongly imbued with the idea of "strengthening medicine," and yet a physician would be puzzled to give a definition of such Dr Cheadle draws attention to the general want of discrimination in giving tonics, or rather the lack of suitable preliminary treatment before the administration of such drugs as strychnia iron, or arsenic The sense of debility experienced by patients is frequently caused by the accumulation of waste products in the body and these must be eliminated before the ordinary "tonics" can exert their beneficial effects

The lecture on the Clinical Uses of Opium will also be found instructive, the indications for and against its employment being clearly laid down

Two lectures are occupied with the discussion of Some Practical Points in the Treatment of Diseases of the Lungs and Air-passages We can cordially recommend a perusal of Dr Cheadle's remarks to young practitioners The methodical treatment of bronchitis is of the greatest importance, whilst the routine method of prescribing "ipecacuanha, squill, and ammonia" in all cases of bronchitis and in all stages of the disease cannot be productive of successful results and certainly cannot be regarded as a high form of medical art The author therefore details the various therapeutical measures which should be adopted in treating a case of bronchitis from the commencement of the attack Equally good are the remarks on the treatment of pneumonia and pleurisy.

Twenty years ago Dr Cheadle first drew attention in this country to the occurrence of scurvy in infants in sporadic form In Chapter IX he gives the results of his large clinical experience on this condition He remarks that the earlier observers in Germany regarded and described infantile scurvy as an acute form of rickets, but the essential independence of scurvy has been generally accepted by the leading authorities in Europe and America He enters fully into the considerations which led him to adopt this view. An interesting table is given of 61 cases of infantile scurvy showing the age at which the disease appeared, the exact diet of artificial food on which the scorbutic state followed in each instance, and the result of treatment by anti scorbutic diet

The lectures on the Rheumatism of Childhood are too well known to need any further remarks from us in order to indicate their object and scope

---

Thomas Sydenham By J F PAYNE, M D Oxon London · T Fisher Unwin With a Frontispiece Large crown 8vo 1900 Pp xvi-264 "Masters of Medicine" Series Price 3s 6d

IN the Oxford Museum—an allegory in building invented by Acland and Ruskin, which forms part of a plan to represent the whole orderly creation, the Kosmos, in such a way as to make it intelligible to the student—the history of medicine is represented by five statues Sydenham, the typical practitioner among the moderns, stands in the centre On his right is John Hunter, who for the interpretation of disease, its causes, its prevention, and its cure searched through every form of life in the great Book of Nature On the other side of Sydenham stands Harvey, who solved the problem that had been unsolved from all time These three built on the foundations reared by Aristotle and Hippocrates, who complete the story

Dr Payne in his account of Sydenham has shown how he brought back the exponents and students of physic to observation and its conclusions and removed them from speculations without data and from misinterpreted authority No living physician is better fitted for this task than is Dr Payne, the Harveian Orator who spoke of Harvey and Galen, and the author of the introduction to Linacre's translation of Galen's "De Temperamentis" Dr Payne, too, is the Harveian Librarian at the Royal College of Physicians of London and was formerly a Fellow of Magdalen College, Oxford, and Sydenham was intimately connected both with London and with Oxford Dr Payne has been at much trouble to construct his biography from original sources and he has been so successful that he has produced one of the most readable, as it is certainly one of the most scholarly, volumes which have as yet appeared in the series of "Masters in Medicine" He traces out the early and adventurous history of his hero with the greatest care and adds innumerable fresh incidents in Sydenham's career

Thomas Sydenham was baptized on Sept 10th, 1624, and died on Dec 29th, 1689 He came of an old Dorsetshire family, being the fifth son of William and Mary Sydenham of Wynford Eagle, a hamlet lying about eight miles from Dorchester From the beginning of the Civil War the father and his sons fought against the King and in the summer of 1644 Mrs Sydenham, the mother, was killed by Royalist soldiers In the following February Francis, a major in the Parliamentary army, was killed in battle William, the eldest brother, was a well known Cromwellian colonel, at one time in command of all the Parliamentary forces in Dorsetshire and afterwards of sufficient importance to be specially exempted from the Act of Indemnity passed when Charles II came to his own again Thomas bore arms under his brother in the campaign in the west and again in 1651, when he was a captain of horse and rendered important services to the Council of State, though, fortunately perhaps, he was absent from England at the time of the Restoration In the Scotch campaign John, another brother, was killed, and Thomas petitioned the Protector for the arrears of his brother's pay At Cromwell's special desire £600 were ordered to be paid to Sydenham out of certain moneys belonging to the Commonwealth in the hands of the commissioners for coal dues in the port of Newcastle The £600 served Sydenham for a marriage portion, as Dr Payne very acutely suggests, and he shortly after settled down to the practice of physic as a means of livelihood So stirring an introduction to life was not without its effects upon the character of Sydenham, and Dr. Payne is careful to point out that "if tales of fighting and bloodshed should seem to be of little moment in the life of a physician we should remember that this rough school of warfare formed a part of Sydenham's education. It was essentially a school of revolt, good or bad as we may choose to think it, and must have had a share in forming the character of one who brought into matters of thought and science the courage of a soldier and the independence of a rebel."

Sydenham received a broken education at Oxford, first at Magdalen Hall and then at Wadham, the home of those who founded the "Invisible College"—as the Royal Society was called at the beginning of its career—and afterwards he became a Fellow and Bursar of All Souls. He was created a Bachelor of Physic in the University on April 14th, 1648, by command of the Earl of Pembroke, when he was still at the commencement of his medical studies, and it was not until June 25th, 1663 that he obtained a licence to practise from the Royal College of Physicians of London. In the interval he had been a candidate for a seat in Parliament; he had filled the office of Controller of the Pipe, or Registrar of Leases granted by the Crown, and, more than all, he had visited Montpellier and learnt his business at the feet of Barbeyrac

The Great Plague of 1665, by enforcing a holiday, led Sydenham to write his first book, a small octavo of 156 pages, which would make two longish articles in a modern medical journal. It was a treatise on Fevers the outcome of his own observations, and he dedicated it to Robert Boyle. Several shorter contributions followed from time to time, though Sydenham was not fond of writing and ill-health and want of leisure made composition difficult to him. From these shorter writings comes his classical account of gout, to which he was a martyr for many years, and we learn that he gave steel filings as a chalybeate and introduced a fluid laudanum—still known as Sydenham's laudanum and analogous to the wine of opium—in preference to the solid laudanum which had been hitherto prescribed. All the writings are in Latin, and Dr. Payne again examines the vexed question of the language in which Sydenham wrote. He arrives at the conclusion that it was terse English translated and amplified for the press by Dr. Mapletoft, one of his medical friends, and by Mr Gilbert Havers, a non-medical graduate of Trinity College, Cambridge.

Whilst Dr. Payne gives Sydenham every credit for the great advances he made in the study of medicine he is quite impartial and shows the points wherein he was ignorant He failed entirely to perceive the importance of anatomy and physiology He spoke with great contempt of morbid anatomy, saying that "others have more pompously and speciously prosecuted the promotion of this art [medicine] by searching into the bowels of dead and living creatures, as well sound as diseased, to find out the seeds of disease destroying them, but with how little success such endeavours have been and are likely to be attended, I shall in some measure make appear." It was the especial merit of Sydenham to proclaim the great truth that science was, is, and always must be incomplete, and that danger lurks in the natural tendency to act upon it as if it were complete. Dr. Payne, therefore, well says that whilst Harvey was the master of science Sydenham was the master of practice

Dr. Payne introduces many interesting incidents into his work He gives an account of the condition of Oxford and of the origin of the Royal Society, he paints a picture of the physician's practice in the seventeenth century, and he tells many good stories. Amongst others he says that Sydenham was one day sitting at his open window in Pall Mall overlooking the Mall in St. James's-park (for the south side of the street had not yet been built) "with his pipe in his mouth and a silver tankard before him, when a fellow made a snatch at the tankard and ran off with it. Nor was he overtaken before he got among the bushes in Bond-street, and there they lost him."

The portrait placed as a frontispiece is from a direct photograph of the painting in the possession of the Royal College of Physicians of London, which is, according to the highest authorities, the work of Mrs Mary Beale, whose son, Bartholomew, was one of Sydenham's pupils.

The biography is dedicated to Sir Samuel Wilks, and the author expresses his indebtedness to Dr. J. B Nias for placing at his disposal some notes on the Sydenham family. As in the other volumes of the series the book is provided with an excellent index.

Kurzgefasstes Lehrbuch der Kinderheilkunde fur Aerzte und Studierende. (A Concise Text-book of the Therapeutics of Children's Diseases for Practitioners and Students.) By Dr. CARL SEITZ. Second edition, enlarged and revised. Berlin: S Krager. 1901. Super royal 8vo. Pp. 499 Price 11s. net.

WHEN the author was invited by the publisher to write a compendium of children's diseases his original idea was to produce for the benefit of students and practitioners a guide in which, firstly, the clinical aspects of these maladies should be portrayed fully and yet concisely, and in which, secondly, special attention should be paid to the physiological peculiarities, hygiene, and dietetics of childhood, and to the methods of examination. It was found that even by discussing these subjects with extreme brevity the limits of a compendium were exceeded and the book had to be written on a larger scale. In this, the second edition, it has widened its borders still further in order to keep pace with recent advances in our knowledge of the complaints of childhood. The chapters on diphtheria, tubercle, rickets, and morbid changes in the blood have been revised and enlarged; additions have been made to the sections on cerebro-spinal meningitis, diseases of the nose, throat, and larynx; while the paragraphs on general defective vitality, chondrodystrophia and osteomalacia are altogether new. The size of the book remains unaltered owing to the employment in several places of smaller type.

We have found the book as a whole disappointing, the result probably of the conditions under which it has been written. The author, we think, has fallen between two stools. His book has ceased to be a compendium and has not yet become precisely anything else. It has, at all events, deviated from the somewhat narrow path on which it appears to have set out and shows a decided tendency to become a systematic text-book of children's diseases. Of this altered inclination the title-page seems to be unaware for it continues to assert that the subject of the volume is the therapeutics of children's diseases. The result of this discrepancy is to render the task of criticism a somewhat difficult one. Do we criticise the author's pathology and symptomatology? The title-page reminds us that the book only professes to be a text-book of therapeutics. A consideration of the amount of space devoted to systematic description, however, shows this position to be untenable—for example, of seven pages devoted to tuberculous meningitis only one is occupied with treatment. Of nine pages on scarlet fever two are concerned with prophylaxis and treatment. Of some 18 pages given to diphtheria only seven deal with these points. Do we ignore the pathology and symptomatology? In a volume of 499 royal octavo pages devoted principally to the therapeutics of children's diseases we have a right to demand a fuller treatment of this subject than obtains in this volume. No student, however, need be deterred from reading Dr. Seitz's book by the suspicion that it is written on too elaborate a scale, for, as a matter of fact, the author's directions as to treatment are quite simple and straightforward. So far, indeed, from being too elaborate, they even share the defects of the systematic portion—that is to say, they are marred by a certain superficiality reminiscent, perhaps, of the origin of the work. The trail of the compendium, if we may be allowed the expression, is over them all.

The book is divided into two parts, the first of which is distinctly the better of the two. It treats: 1. Of the physiological and anatomical peculiarities of childhood. This section is perhaps the most satisfactory in the book. 2. Of the rules according to which children should be fed and clothed. Here some useful tables will be found. One gives an analysis of 35 infants' foods; another of 70 common articles of diet in reference particularly to the proteids, fats, and carbohydrates which they contain In this section we find no fewer than 16 ways of preparing food for bottle-fed infants, and apparently the practitioner is supposed to try the various recipes in turn till he happens to light on one which suits his patient Compared with the scientific yet simple methods advocated by Rotch and other Americans Dr Seitz's plan seems somewhat crude 3 Of methods of examination which are also well described. 4. Of the general principles of treatment. Here the author rightly emphasises the value of hydrotherapeutic and other non-medicinal remedies in infancy.

Part II. is devoted to the consideration of individual diseases in detail, and it is here that the superficiality which we have referred to becomes most apparent Only half a page is devoted to the etiology of rickets, and it is nowhere suggested that an insufficiency of fat in the food may have anything to do with the causation of the disease. While other factors, such as unhygienic surroundings and wasting maladies, play their part, a theory as to the pathogenesis of rickets which is supported by much evidence should not have been entirely ignored. In the treatment of ordinary cases besides phosphorus, adrenal substance and thyroidin are recommended. Under "General Defective Vitality" Dr. Seitz groups those children who without discoverable organic defect are congenitally unfitted to assimilate sufficient nourishment—cases, in fact, of atrophy which are not the result of dyspepsia, a convenient distinction.

We think that the author could make a fine text-book of this volume. We have pointed out its defects, and in its next edition we hope to see them removed.

On Diabetes Mellitus and Glycosuria. By EMIL KLEEN, Ph.D , M.D. London · Baillière, Tindall, and Cox. 1900. Pp. 313. Price 10*s*. 6*d*.

DR. KLEEN'S experience as a physician in Carlsbad has given him exceptional opportunities to study the occurrence, symptoms, pathology, and treatment of diabetes and the present volume is the result of his observations and experiments.

The author very rightly takes a broad view of the subject and he is to be congratulated on the way in which he has set forth the conclusions at which he has arrived. We note particularly the stress which he lays on glycosuria as a condition apart from true diabetes mellitus. Under the latter condition are usually included different pathological conditions which are imperfectly understood but which are characterised by a faulty metabolism as a result of which, under ordinary diet, there takes place the excretion in the urine of an abnormally large amount of sugar. Thus diabetes mellitus is not a clinical unit but a syndrome, the chief and most constant symptom of which is glycosuria, which is represented by very varying clinical types As Dr. Kleen points out in his first chapter, there are numerous cases attended with the excretion in the urine of minute yet distinctly pathological amounts of sugar, which cases differ widely in clinical aspect and in prognosis from the diabetic type, and which should not be included in the designation "diabetes mellitus," and it is more particularly from the point of view of prognosis that the practitioner will do well to carefully observe and classify all cases which yield proofs of the presence of sugar in the urine When the power of consuming the ingested and digested carbohydrates is but little, or momentarily, impaired, and when the pathological excretion of sugar under ordinary mixed diet only slightly exceeds the traces of sugar found in normal urine, or is but transitory, the condition must not be considered one of diabetes mellitus, but of simple glycosuria. When, however, the excretion of sugar becomes considerable and more persistent but disappears when the carbohydrates are decreased or withdrawn from the food, the condition then prevailing, and which generally is accompanied by other more or less well-defined symptoms, Dr. Kleen suggests should be known as the "mild stage of diabetes," whilst he considers that the severe stage of diabetes is characterised by the occurrence of glycosuria even when the carbohydrates are withdrawn from the food. We quite endorse this classification, although the limits thus fixed are far more distinct on paper than in the reality of clinical experience.

The chapter on the Geographical Distribution of Diabetes Mellitus contains much interesting information. Of all races, the Hindu is most susceptible to diabetes. One authority (Bose) estimates the number of deaths from diabetes in Calcutta at 10 per cent. of the entire mortality. Next to the Hindus the Jews are highest in the scale of diabetic frequency. Dr. Kleen has come to the conclusion, from the researches of Abeles, Meritz, and others, and also from his own investigations, that there is a trace of glucose in normal urine and that the amount in 24 hours scarcely exceeds one-thousandth of 1 per cent. Some slight or occasional increase beyond this may often occur without noteworthy significance, but as soon as hundredths or tenths per cent. are reached the condition must be considered pathological.

Dr. Kleen further points out that although simple glycosuria often shows a decided tendency to remain unaltered for decades in spite of all sorts of pernicious influences, yet mild diabetes certainly not infrequently develops gradually from simple glycosuria, but it usually remains of the mild form.

The chapter on the Symptoms and Complications of Diabetes Mellitus is well written. The descriptions are full and complete and the illustrative cases are printed in a different type to that of the general letterpress—a plan which has obvious advantages There is also a short, but interesting, chapter on "Diabetes Infantilis."

The theory and pathogeny of diabetes are discussed under the heading of "Metabolism and Nutritive Needs." The amount of work required in preparing material for this chapter must have been immense and we can strongly recommend a perusal of it to those who wish for a thorough knowledge of the subject

Some useful hints are given in Chapter VIII., entitled "Investigation of a Case of Diabetes," the first and most important rule being never to use for a test a specimen of urine passed when the patient's stomach is empty before the first meal of the day. This is a point which is frequently forgotten, with the result that a false impression of the case is received.

In the last chapter the principles of the trea
diabetes mellitus are clearly and succinctly lai
rational diet must be followed, rather than

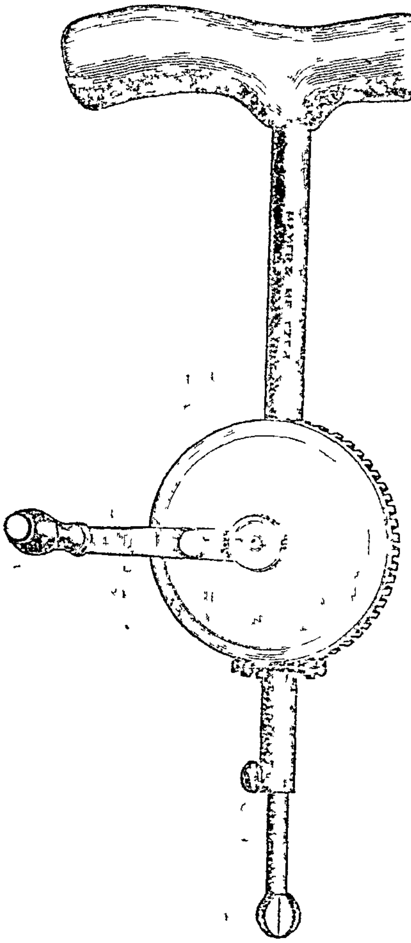
successful treatment of diabetes. Dr. Kleen's directions will well repay study, and we can recommend this volume to those who seek information on all matters connected with glycosuria and diabetes.

New Inventions.

DRILL FOR MASTOID CASES.

MESSRS MEYER and MELTZER have made for me a modified form of drill for mastoid cases shown in the annexed diagram. By the arrangement of toothed wheels I find it quite easy to rotate the burr at 1000 revolutions per minute. The length of the shaft and the shape of the handle enable one to give very accurate directing power and



The burrs fit into a square socket, so that
s may be used. While not to be compared, of

RESSINGS.

dressings which we
Son, Limited, of
5, Fann-street,
packed for
erilised by

steam and packed in cases all sterilised in the following manner. The dressings are cut and folded to the size required and then inclosed in the patent container which consists of an inner wrapper of parchment paper. Outside this is a wrapper of grey waterproof wool and outside this, again, is an outer wrapper of glazed paper. The whole is sterilised by means of steam under pressure In order to avoid the contents getting moist the apparatus with the dressings inclosed is heated, after shutting off the steam, in a vacuum The packets are then taken out and sealed under strict aseptic precautions. This step of obviating the appropriation of moisture during the process of sterilisation by steam is of course important, as all surgical dressings are much more effective when used quite dry. We have received two typical samples of cases thus prepared, but amongst the series provided by this firm are an amputation set large and small, a breast cases set, an excision of glands set, a minor operation set, a skin-grafting set, a hernia set, a trephining and mastoid set, and an abdominal section set. Most of these comprise, of course, absorbent sponges, absorbent wool, gauze, and bandages. This method of packing aseptic dressings is fully in accordance with surgical requirements.

NEW FRÆNUM SCISSORS.

THESE scissors, which I have designed and which Messrs. Mayer and Meltzer have kindly made for me, consist of upper and lower blades. The upper one is fashioned in the ordinary way; the lower blade is much broader and is divided nearly up to the pivot-joint into two portions, with a slight interval between them The left portion, together with the right, form a director and guide, whilst the right portion alone opposes the upper blade and forms the cutting surface. By this means the operation of severing the frænum linguæ can be performed with one hand, whilst there is no danger of wounding the lingual vessels.

THE "CLARATMOS" PATENT VENTILATING SCREEN.

THIS screen effects two things: firstly, it filters the air, and, secondly, it disperses a draught so that the current of incoming air is diffused and no unpleasant cold currents are experienced. It consists simply of a frame containing two sheets of metal gauze of a certain mesh which is easily attached to the ordinary window fittings. Between the pieces of metal gauze is placed, also, a gauze of fabric like Gamgee tissue. If desired this may be impregnated with some antiseptic. In order to place the screen in position the lower sash is raised and the frame is introduced into the grooves provided for the upper sash. The screen is secured by means of wedges at each end The window can be opened or closed as usual by gently pressing the sash past the rubber flange provided. The screen is so devised as not to interfere with the free passage of incoming air, whilst it filters it from suspended impurities, as is evident from the accumulation of dirt upon it. Again, the screen acts as a resistance *and* thus prevents a draught. The patentees are Messrs. F W. Warren and Co., of 340, Harrow-road, London, W.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 24, 1900.

THE Local Government Board recently issued a new General Order on workhouse regulation with special reference to dietaries to take effect from and after March 25th, 1901, or, at the option of the guardians, from and after Dec. 25th, 1900. The Order is worth the close attention of all our readers. Dietaries are difficult things to devise where large numbers are concerned and where economy is a consideration, and the dietaries in the schedules of this Order must be tested ultimately by experience. But it seems not premature to say that the Order and the circular accompanying it show that the Local Government Board have taken into due consideration all the points involved in the fitting solution of such a problem as the proper feeding of the poor in workhouses, whether able-bodied or otherwise. The Board have, of course, acted under the advice of a committee appointed for the purpose and of their medical inspectors, Dr. A. H. DOWNES and Mr. A. FULLER.

The first points in devising such dietaries is the sufficiency of any dietary to meet the necessities of nutrition of the inmates, and the provision of sufficient variety in it from day to day. If there may not be luxury in workhouse fare there is at any rate no excuse for a sickening uniformity *to intensify the monotony of existence in workhouse conditions.* To judge from the experiences of inmates of public institutions generally there seems to be extraordinary difficulty in giving interest and variety to meals. We suspect that this often arises from apathy or want of imagination or liberality in those who have to provide the food. It is, *at any rate so far as* the complaint is well founded, inexcusable, for the greater the number that have to be provided for the easier it should be to provide cheaply or reasonably a sufficient variety of good food. The next point is that there shall be no waste. The fourth point is that the medical officer shall have a general authority over the dietaries and a special one in favour of several classes which naturally fall to be protected by him, notably the sick, the very young, the insane, the feeble, the pregnant, and also those unfortunate individuals who have idiosyncrasies of appetite and to whom the ordinary fare is unsuited. Finally, there is that great question in diet—the use of alcohol. These are the principal points to be faced in any Government regulation of workhouse dietaries, and they have been met in the new Order and disposed of in a way fair to the poor and to those at whose expense the poor are fed; the discretion of the medical officer in regard to the dietary of his patients has been practically uninterfered with.

While there is no justification in a workhouse for excess or for luxuries there is no reason why the food should not be pleasant and acceptable and sufficient. We think that this is provided for in the dietary of the able-bodied and in that of the sick also in the new Order. Medical men and experienced matrons who have knowledge of the food-supply of their own houses would say that the rations and the ingredients of the rations are satisfactory and are certainly superior to anything that the class of persons usually found in a workhouse would be able to command at home. In the breakfast and supper rations of a plain diet for able-bodied men and women, whether at work or not at work—of which 11 varieties are given—it is specially provided that the rations are to be so selected that the breakfast and supper shall not be alike on any one day. For an able-bodied inmate at work an additional meal in the form of lunch is provided. It seems to us to be a defect that in the breakfast of the able-bodied no coffee, tea, or cocoa is provided. A very large proportion of the inmates of workhouses are reluctantly obliged to do without alcohol and it seems to us a little severe that they should not be provided with the nearest substitute in the shape of non-alcoholic stimulants. On Sundays only, with *bread-and-butter, or margarine,* a pint of tea or coffee is provided. In the corresponding meals for children the liberal proportion of milk in coffee, tea, or cocoa is a good feature. The list of rations for dinner in the plain diets for able-bodied men and women, whether at work or not at work, contains no less than 39 varieties. It includes dinners of roast or boiled beef, mutton, and pork with bread and vegetables; boiled beef with suet pudding, bread, potatoes, and other vegetables; tinned meat, bacon, hashed meat, fish, soup, Irish stew, hotch-potch, meat pie, and potato pie. The large range of possible menus thus suggested gives a pleasant impression of thoughtfulness in those who have constructed the formulæ. And this impression is confirmed by a study of the various dinners, 24 or 25 in all, supplied to the infirmaries. Here the meat course is supplemented by 13 puddings, roley-poley, golden pudding, bread pudding, batter pudding, and the like, names which suggest the disposition to supply the infirm with convenient and even enticing food. The dietaries for children are equally satisfactory. In this connexion it is to be noted that children are not to be served slavishly by weight but according to their appetite, and that in regard to children under three years of age *and in infirmaries or* sick wards the medical officer has authority to empower the nurse to make modifications.

One of the most important points in the dietary of workhouses is the use of alcohol by the inmates. The authority of the medical officer with regard to all questions arising here has to be defined. The matter is carefully handled in the General Order and on the whole is dealt with in a way of which the profession cannot complain. The classes which go to make up a workhouse population are much addicted to the abuse of alcohol and the habitual use of it in workhouses is now discontinued. Article VIII. of the Order says that the guardians shall not allow to any inmate any fermented or spirituous liquors unless in pursuance of a written recommendation of the medical officer for the workhouse, to be entered in a book termed "the alcohol book" and to be accompanied by a statement of his reasons for such recommendation. We approve of this regulation the more entirely because the next paragraph of the article maintains intact the absolute discretion of the medical officer in respect of the prescription of alcohol for the sick, while other articles give a large power to him to vary the diet of inmates of the workhouse temporarily for sufficient reasons. Some intemperate teetotalers would wrest from the medical man the power of prescribing alcohol even for the sick; but such views receive no sanction from ordinary sensible people. We see in Article VIII. a proper recognition of the exceptional place of alcohol in diet and therapeutics. This it is which throws a great responsibility on those who prescribe it.

To speak generally, the thoughtfulness shown in preparation of the new General Order is obvious. It finds a further illustration in Article V., which empowers the master of a workhouse when satisfied that the inmate, though not ill enough to need medical attendance, is unable to take the ordinary ration to order him a lighter meal, the occurrence to be reported to the medical officer at the next visit for his confirmation and comments. We have nothing but approval for the constantly reiterated instructions in this Order against waste. The food that is not consumed after any given meal has to be kept for early future use, while daily and weekly accounts by the master of the workhouse relating to provisions issued from, and returned to, the stores have to be prepared. The master is also to keep a careful record of the diets ordered by the medical officer under Article VII. in the special cases already enumerated. The General Order, in fact, emphasises the responsibility of the medical officer in the matter of dietaries. It imposes on him the duty of advising the guardians in the adoption of the tables of ordinary diet as well as the duty of giving special heed to the diet of the sick and the young.

◆

THE autumn session of the General Medical Council will commence on Tuesday next, Nov. 27th, at 2 P.M. There will be several differences in the *personnel* of the Council. Changes have taken place in the representation of the Victoria University and of the Royal College of Surgeons in Ireland. The late Dr. D. J. LEECH, a most valuable member of the Council, is now replaced by Professor A. H. YOUNG, and Sir PHILIP SMYLY yields his seat to Dr. C. B. BALL The absence of Sir PHILIP SMYLY at the time when questions in which he was personally interested, deeply involving the interests of the Branch Council of Ireland, have to be discussed, is unfortunate. But the most startling novelty in the composition of the Council will be the appearance at its deliberations of a representative of a new University, one which has not yet any medical graduates and which can only have them for five years by retrospective action. The situation must appear to many open to criticism, but it is not likely to be the subject of any serious discussion at the Council table. There will be some indirect advantages in the presence *ab initio* of a representative of the University of Birmingham. He will become the sooner acquainted with the educational views of the Council and with its general business, and will be the readier to introduce into the Council's methods that energy and practical spirit which, when kept within bounds, we all admire in the Midland metropolis.

It is possible that the session may be a short one compared with its immediate predecessors, both of which have extended over eight days. A vigorous effort should be made by the Council to curtail its proceedings. It would gain credit by greater dispatch in the conduct of business and would save money—an object which for urgent reasons should be kept in the front. Without attempting to mention all the subjects which must engage the attention of the Council we can form a pretty fair estimate of the principal of these. Three or four matters will certainly call for careful handling. They have already occupied much of the time of the Council and should be disposed of in such a way as not to be troublesome again. One of these matters is the dispute between the Royal College of Physicians of London and the Royal College of Surgeons of England on the one part and the Council on the other, touching the registration of medical students and the recognition of science teaching. The teaching given in certain schools is recognised as being up to the standard required for the medical curriculum by the Colleges but not by the General Medical Council which does not regard the schools as being universities, or schools of medicine, or scientific institutions. There is something to be said on both sides, but the dispute has lasted too long and should be closed. It is the perpetual carrying over of contentious business from session to session that is responsible for so much waste of time and money. At the last meeting of the Council the President, acting on the suggestion of the Education Committee, undertook to get an opinion from Mr. MUIR MACKENZIE on the legal points raised. It is a pity that such guidance was not obtained at the outset, but it is understood that Mr. MUIR MACKENZIE's opinion has now been received and the Council will doubtless be guided by it as to any further controversy with the Colleges. The Colleges are very tenacious of what they believe to be their rights, but they will be more likely to be influenced by the Council if it acts strictly within the lines of its legal powers.

The most important subject to be considered by the Council at its approaching meeting is its own financial position, which last session was referred for further investigation to a special committee. The report of this committee cannot fail to be of much interest, for the particulars of the exact financial position of the Council at the present moment will there be given. The figures cannot differ materially from those contained in the last report of the Financial Committee in June, which showed the tendency of the expenditure of the Council to grow, while its income for the moment tended to diminish. The excess of expenditure over income, which amounts on the average of the last seven years to £677 a year, is easily explained. The range of work done by the Council has largely increased; the sessions have grown longer; every committee makes its reports and expects them to be published; the inspection of the examinations of the Apothecaries' Hall of Ireland has been costly; the premises of the Council have been enlarged and a sinking fund has been established for the extinction of the debt. Much legitimate progress is implied in most of these items of expense. But it is unsatisfactory that the capital of the Council should be drawn on to the extent of over £600 a year and some scheme of economy must be devised. The impecunious condition of the Irish Branch Council is very unsatisfactory and the dole out from the General Medical Council for temporary relief is more so The Irish Branch Council should cut its coat according to its cloth as the English and the Scotch Branch *Councils do, and contrive to have a balance on the right* side It may, however, be necessary to bring the Branch Councils under a common and central financial arrangement

◆

DR JOHN CLARK of Cleator Moor, Cumberland, has written to us on the subject of additional fees for adjourned inquests alluded to in our second leading article of Nov 3rd He reminds us of a letter which he published in THE LANCET of Feb 12th, 1898, p 480, signed "M D," to which, and to our reply to it, he refers us Briefly the facts are these On Jan 28th, 1898, Dr CLARK was asked to attend a coroner's inquest *on the body of a woman who died under peculiar* circumstances, he attended and gave his evidence, but the jury *not* being satisfied unanimously demanded a post mortem examination, which Dr CLARK duly made *after receiving formal request from the coroner to do so* and to give evidence thereon On the coroner paying the usual fees of two guineas one for making the post-mortem examination and one for giving evidence, Dr CLARK claimed *three guineas, basing his claim on the statement* in Wellcome's Medical Diary (1898), page 211 He considered himself entitled to one guinea for attending the inquest in the first instance and giving evidence and to two guineas in addition *for* making the necropsy and giving evidence thereon The coroner declined to pay more than two guineas, which Dr CLARK accepted without prejudice, telling the coroner that he (Dr CLARK) would look further into the matter *In reply to the question as to whether he was entitled* to three guineas we felt obliged to reply in the negative and to express our belief that the coroner was right We now learn from him that he subsequently succeeded in getting the extra guinea on applying to the county council, who decided in his favour But as the coroner pointed out, "the Act is not without doubt,' and he required a promise from Dr CLARK that he would return the fee should the auditor surcharge him Subsequently he received an order from the same coroner to make a post-mortem examination and to attend to give evidence He did so, the inquest was adjourned and he was required to attend again, being detained six hours He again claimed an extra fee from the county council, but this time without success On applying, however, to the Home Office he received a reply that his letter would be attended to, and after the lapse of a few months he received a cheque from the coroner for one guinea *He also* informs us that another practitioner in his neighbourhood was equally successful Dr CLARK truly observes that we are unaware of such extra fees having been paid to medical men and he justly *considers* that the *profession* ought to know of such demands and concessions While perfectly agreeing with him and giving him and his friend, as our readers will, every credit for the stand which *they successfully made*, we must remark that the county councillors were exceptionally generous in the first instance Why did they not repeat this generosity in the second case? It is more than probable that they had discovered that the Coroners Act of 1887 allows a *fee* of two guineas only, and that their functions as county councillors were limited to being just rather than generous The Home Secretary is in a different position, he having power to order additional or *special fees* to medical witnesses But would many medical men undergo such worry and such delay for a claim even when they considered it just? We think it preferable to get the Act amended

The section of the Coroners Act, 1887, which fixes the amount of fees is as follows A legally qualified medical practitioner who has attended at a coroner's inquest in obedience to a summons of the coroner under this Act shall be entitled to receive such remuneration as *follows* that is to say, (*a*) for attending to give evidence at any inquest whereat no post mortem examination has been made by such practitioner, one guinea, and (*b*) for making a post mortem examination of the body of the deceased with or without an analysis of the contents of the stomach or intestines and for attending to give evidence thereon, two guineas It is perfectly clear that the coroner possesses no power whatever *to pay any fee for a second attendance upon an* adjourned inquest, and, knowing this, the general practice of coroners in cases of murder, manslaughter, and others, where an adjournment is inevitable, is to take evidence of *identification of the body only at the opening of the inquest*, the medical witness not attending till the adjournment In a large proportion of adjourned inquests one attendance only is required, but it not unfrequently happens when there are many witnesses that a second or even third adjournment becomes necessary, and as the evidence of the medical witness is always taken last he must be present at the end We have already condemned the half-guinea police court fee as a paltry one to offer to a professional gentleman, and the same remark applies to the coroner's court Sir MATTHEW WHITE RIDLEY having *resigned the office of Home Secretary* he has been succeeded by the Right Hon C T RITCHIE to whom we hope an earnest and successful application will be made for a revisal of fees to medical witnesses in all courts of law

Annotations.

"Ne quid nimis."

THE ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

It cannot be said that the proceedings at the annual meetings of the Royal College of Surgeons of England are remarkable either for interest or importance The only motion of any real moment at the last meeting was that in which an appeal was made to the Council to confer representation *on the Members* With this appeal we need hardly say that we cordially agree, for we have ever maintained that the Member of the College has an inherent moral right to a share in the government of the corporation of which he is a part, although by the Charter of 1842 he was deprived of the franchise The motion was carried without a dissentient vote but if we may judge by precedent it will be of no effect At present the real obstacle to any further progress in this direction is the adverse vote recorded by the Fellows in 1896 The time has now, however, arrived when another that it should be given throughout the whole of the City We are glad, however, to note that the correspondent of the *Times* asserts that "in all the streets and public ways of the City the New River Company have constantly charged mains to which at short intervals the public fire hydrants are fixed." The statement would have been even more satisfactory had it been directly given by the New River Company. A small part of the City is supplied by the East London Waterworks Company and if, as it is asserted (by the correspondent of the *Times*), the New River Company supply water for fire extinction in the area supplied by the East London Company they deserve the thanks of the citizens who dwell there. Is it possible that the *Times* correspondent was mistaken in this particular?

FIGHTING AGAINST TUBERCULOSIS.

THE French Society of Preservation against Tuberculosis caused handbills to be distributed at the doors of the Paris Exhibition. In these handbills it is stated that in the course of the year 150,000 persons died from tuberculosis in France. The loss due to this disease alone is therefore equal to all the inhabitants of such a town as Toulouse. More than plague or cholera, more than all the epidemic diseases put together, is tuberculosis fatal to the population. Then advice is given as to the prophylactic measures that should be taken, and the handbill urges that spittoons should be placed everywhere—in factories, workshops, offices, shops, barracks, hotel rooms, theatres, schools, railway stations, and the like—and that those who are obliged to expectorate constantly should carry pocket spittoons with them. This advice is being adopted to some extent. In the Paris omnibuses and other places of public resort there are notices requesting the passengers not to spit on the floor and the number of spittoons at the disposal of the public is daily increasing.

THE HARVEIAN LECTURES OF THE HARVEIAN SOCIETY.

THE series of three Harveian Lectures delivered by Dr. Robert Maguire will be published in full in THE LANCET. Without anticipating what our readers will find in the full account (delayed in publication by the advancement of date of the lectures) we may at once call attention to the matter of the third lecture, which deals especially with the Treatment of Pulmonary Tuberculosis. Dr. Maguire gave an account of the experiments which he had made upon animals and upon himself as to the effects of remedies administered intravenously. The pulmonary circulation lends itself, as he showed, to the treatment of this disorder, for whatever can be injected into the veins must first find its course through the lungs by way of the pulmonary artery. Therefore remedies which might be injected by this method would have a more pronounced effect upon the lungs than those administered by the skin, by the mouth, by inhalation, or by direct injection into the tissues of the lungs, as Dr. Maguire discussed. The dilution of the remedies as administered by such previous methods must be obvious. But it is not asy to find a germicide, of whatever nature, which can be safely injected into the veins and in such strength as to be fatal to the germs contained in the lungs. Dr. Maguire tried cyanide of mercury and potassic iodide of mercury, but with no good results. He also tried solutions of diastase and of nuclein, but with no result which would encourage further procedure. At last, however, he attempted the use of tricresol and finally of formic aldehyde. The latter re-agent he first used in a strength of 1 in 250,000, but after repeated trials found that he could use it in a strength of 1 in 2000, and by special apparatus could inject with safety 50 cubic centimetres of this solution daily. The technique requires care. Dr. Maguire had calculated the strength of the solution which would reach the lungs, on such a solution being injected into the veins, and showed that it was likely to be an efficient germicide He had found on his own person that greater strength of solution, or a greater amount of the solution named, was dangerous He described the effects of such injections, as practised by himself and others on some 70 patients, and mentioned that the patients so treated had greatly improved, and that many of them had shown disappearance of tubercle bacilli from the sputum. One of such patients, apparently cured, was brought before the meeting of the society at which the lecture was delivered. Also Dr. Maguire said that similarly good results had been obtained in putrid bronchiectasis and the treatment was likely to be of use in acute pneumonia

THE BATTLE OF THE CLUBS: A SUCCESSFUL PRECEDENT.

THE medical men of Eastbourne were among the first to show the practicability of organising the profession so as to secure effective action against companies catering for medical work and employing canvassing and other objectionable methods. It is satisfactory to know, from the report read at the fifth annual meeting, that after five years the profession is still loyal to itself and is making a successful resistance through the Eastbourne Provident Medical Association to low forms of medical service. Much of the credit of this state of matters is due to Dr. Alexander Harper He is honorary secretary to the association and is not himself on the working medical staff. The association is now worked with one collector and otherwise expenses are being reduced. The thorny question of wage-limit is not disposed of on any hard-and-fast line, but is left to the absolute discretion of the committee which by the rules must contain two or more representatives of the Eastbourne Medical Society. Practically the unanimity of the profession at Eastbourne is complete and there is a good prospect of their being able to solve the problems connected with medical attendance on the working-classes so as to give little chance to stray companies of the commercial sort and their medical agents.

THE HOUSING OF THE POOR IN LONDON.

THE amendments passed on August 8th last on the Housing of the Working Classes Act of 1890 are so feeble that this important question cannot remain as it is. The recent outbreaks of Hooliganism clearly indicate the development in our midst of a semi-savage population which is a serious menace to the peaceful and lawful citizen. From the social, the political, the military, as well as from the sanitary point of view every endeavour must be made to check the growth of a degenerate and degraded population. The medical officer of the London County Council, Mr. Shirley Murphy, has put the facts plainly before us. Some 400,000 Londoners are living to-day in one-room tenements. Of these 9000 are living seven in one room and 3000 eight in one room. As many as 17 persons have been found *in one room, sometimes* three in a bed and two under the bed. The death-rates in the different parts of London correspond with the overcrowding. In St. George's in the west where 10 per cent of the population are overcrowded the death-rate is 13 2 per 1000; in St. George-in-the-East where 40 per cent. of the population are overcrowded the death-rate is 26 4 per 1000. Improvements have been effected to the advantage of the better class of workmen and of shop assistants and other sections of the community who were in no urgent need of such assistance, but the condition of the extreme poor is, if anything, even worse than it used to be. Mr. Steadman, as a representative of labour in the House of Commons, stated that the London County Council in 10 years had spent £2,000,000 to re-house 42,000 people. But he pointed out that Part I. of this scheme had cost £851,456, and, "out of that sum no less than £282,405 had gone into the pockets of men who, instead of being compensated for their rotten property, should have been prosecuted." Then he inquired why butchers, milkmen, and others who sold unwholesome food should be punished while landlords who let unwholesome dwellings should be allowed to go free. But it is not so much the insanitary character of the dwellings as their overcrowding which does the mischief. The London County Council use the best material and construct substantial dwellings which will probably last from 200 to 300 years and they pay exorbitant compensation to the former owners, and all this very great outlay has to be refunded in 60 years. As a natural result they are obliged to charge high rents, and therefore their re-housing schemes do not bring any relief to the extreme poor. It is true that the new Amendment Act will now enable the London County Council to purchase land and to build houses outside the metropolitan boundaries. There the rents will be lower, but from this advantage must be deducted the cost of travelling and the loss of time which it involves. As a remedy Mr. Steadman proposed that the Government should give facilities for borrowing money at a cheaper rate of interest and that the repayment should be spread over a period of 100 instead of 60 years. But the great stumbling-block is the exaggerated compensation paid to the owners of slum property. Nothing is more profitable than the letting of houses to the extreme poor. The poorer the tenant the higher the rent he pays in proportion to the space which he occupies; but the fact that a large income is obtained by allowing the overcrowding of tenements is not a sufficient reason for paying to the owner a proportionate compensation. In any case the present state of affairs can only be allowed to continue at the peril of the community. As Lord Rosebery truly said: "There is not a close in the darkest quarters of Glasgow or a crofter's cabin in the Hebrides which is not a matter of imperial concern," and he added: "In the great cities, in the rookeries and the slums which still survive, an imperial race cannot be reared."

CHOLERA IN KOHAT.

LAST July a serious outbreak of cholera occurred among the native troops comprising the garrison of Kohat in the Punjab. This has formed the subject of a report by Major R. H. Firth, R.A.M.C., sanitary officer of the Rawal Pindi district. The first cases showed themselves on July 3rd, and from that day up to and including July 19th there were 314 cases and 151 deaths. By far the greater number, both of attacks and deaths, took place between July 3rd and July 13th, after which date the disease rapidly declined. Of the 314 cases 209 were in soldiers, either horse or foot, the remaining 105 cases being among followers. Of the 151 deaths 106 were of soldiers and 45 were of followers. This was the severest outbreak of cholera in any garrison of India which had occurred for many years and it presented three notable features—viz., (1) that although during the period under review there were some 60 Europeans resident in Kohat no single one of these was attacked by cholera; (2) that in one unit—the Punjab Garrison Battery—only one case occurred; and (3) that in another unit—the 19th Punjab Infantry—no less than 126 attacks with 56 deaths were reported. Major Firth and the medical officers of the garrison united in attributing the outbreak to choleraic pollution of the irrigation water which flows freely through Kohat. There was no reported case of cholera either in the city or district of Kohat before July 3rd, but it was well known that cholera existed all over the Punjab in June, and Kohat is the great centre to which the roads lead. The 19th Punjab Infantry suffered most heavily of all. This regiment arrived in Kohat on July 6th and camped on a grass farm near which irrigation water ran. They were free from cholera on arrival, but 26 cases with 11 deaths occurred on July 8th, and 61 cases with 18 deaths on July 9th. It was found that the men had consumed large quantities of the irrigation water. The removal of the corps to a camp away from all irrigation and to a water above suspicion rapidly checked the outbreak. The Punjab Garrison Battery used exclusively water from the fort well and escaped with only one case of cholera, a man who was known to have had close domestic relations with the city. Among the recommendations made by Major Firth with a view to the prevention of similar mishaps is one to the effect that British officers of native corps might show more energy than they do in disseminating ideas of personal hygiene among their men.

GENERAL HOSPITALS AND MENTAL DISEASES.

OUT-PATIENTS suffering from mental disorders have been for long treated at St. Thomas's Hospital and elsewhere. The results of experience have shown that good work has been done in relieving many sufferers and in avoiding the necessity for asylum care in not a few cases. The quarterly court of governors of the Newcastle Infirmary has decided to institute such a department, as reported by the *Newcastle Evening Chronicle* of Nov. 1st. Dr. G. H. Hume, in bringing forward the motion, pleaded for the fundamental ideas of prevention and cure, and it has been decided that a physician, qualified as the rules require and occupying an appointment in a public asylum in Northumberland or Durham, should attend at the infirmary one day in each week and prescribe for the out-patients placed under his care.

MEMORIAL TO THE LATE PROFESSOR JOSEPH COATS.

AT a meeting held in the Hall of the Faculty of Physicians and Surgeons of Glasgow on Feb. 7th, 1899, it was resolved to raise a memorial to the late Dr. Joseph Coats, who first occupied the position of professor of pathology in the University of Glasgow, and it was agreed that this memorial should take the form of an endowment connected with his name for the purpose of encouraging research in pathology. Intimation was sent to his colleagues, assistants, pupils, and friends that this opportunity was afforded of testifying to their appreciation of his character and services, and of at the same time forwarding the work to which so much of his life had been devoted. A fund has now been raised amounting to £1243 and the committee representing the subscribers have arranged with the University Court that the University of Glasgow shall found a scholarship therewith. This endowment will be known as the "Joseph Coats Memorial Scholarship in Pathology, founded by the friends of the late Professor Coats as a memorial of his distinguished services to pathological science, and in recognition of the ability and enthusiasm which he devoted to advance the teaching of the subject in Glasgow." The scholarship will be for the encouragement of original research in pathology and will be tenable for one year. It will be of the value of the free income of £1200 for the two preceding years and will be awarded biennially. Candidates must be graduates of medicine in the University of Glasgow of not more than three years' standing, and the scholarship will be awarded by the Senate on the results of a practical examination in pathology conducted in the beginning of October of every second year. The successful candidate must, for not less than six months following the award, pursue research in pathology in the Pathological Institute at the Western Infirmary or in a laboratory elsewhere approved of by the Faculty of Medicine, and shall not engage in medical or surgical practice during this period. In accordance with the above conditions the sum of £1200 has been handed over to the University Court, and in accepting this sum the Court instructed its secretary "to tender to the donors the very cordial thanks of the University for the endowment they have so liberally provided, and to assure them of their keen appreciation of the interest they have manifested in the welfare of the University." There remains in the hands of the honorary treasurer, after the disbursements for printing, advertising, postage, and other small expenses, have been defrayed, the sum of £18 9*s.* 1*d.* With this sum the committee propose to purchase a brass tablet to be placed in the pathological rooms at the Western Infirmary.

THE SCHOOL BOARD ELECTION IN BRADFORD.

WE are glad to see that a medical man is standing as a candidate for the Bradford School Board and also that the medical man in question is Dr. T. W. Hime who was chosen to stand by a largely attended meeting of medical men as well as by a number of laymen. The presence of a medical man upon a School Board is very necessary to curb the zeal of fanatical "educationists" who look upon children merely as grant-earning machines, who fill them with smatterings of some five-and-twenty different kinds of knowledge instead of teaching a few subjects well, and who consider that if a child is well enough to be out of bed it is also well enough to go to school. Dr. Hime's remarks in his address upon over-pressure and the dangers of infection are excellent and we hope that he will be returned. Over-pressure and infection are the chief matters with which we are concerned as regards School Boards, for they affect the community at large With regard to the relations between medical men and School Boards they are also of no small importance to us, and from time to time we have had to say very plainly what we thought upon the matter. Dr. Hime, too, has done good work for Bradford practitioners on the question of payment for certificates and the like, and we are sure that, whether elected or not, he will continue to do so; but if elected he would be in a more satisfactory position than if acting merely as a private citizen.

OPTIC NEURITIS IN MUMPS.

IN the October number of the *American Journal of Ophthalmology* is published a translation of a very important paper on this rare condition which was read at the Section of Ophthalmology at the Thirteenth International Medical Congress by Dr. H. Dor of Lyons. A man, aged 25 years, consulted him on Feb 14th, 1900, for gradual loss of vision which began in April, 1899. In June optic atrophy was first diagnosed. Both optic nerves showed post-neuritic atrophy. Under the application of a constant current of five milliampères and injections of five milligrammes of strychnine vision improved and the patient could count the fingers at two and a half metres with the left eye and at one metre with the right eye. But no further improvement could be obtained. Formerly he was an excellent shot. The most careful investigation brought to light no other cause than an attack of mumps from which he had suffered in April, 1899, during his military service, and which confined him to hospital for 27 days. Optic neuritis in mumps appears to be well known to French military surgeons Thus Surgeon-Major Hatry, who first described it, says[1]: "A soldier came to hospital on account of mumps of both parotid glands. He saw as if in a mist and the white *cornet* of the sister of charity appeared to him blue." The ophthalmoscope revealed changes which were afterwards seen in nine other cases of mumps—hyperæmia of the discs, dilatation of the vessels, and infiltration covering the papillæ. The prognosis in Surgeon-Major Hatry's cases was usually good and vision became normal in about two or at most three weeks. In the milder forms of optic neuritis vision was not much diminished, in the more severe forms it was, and the colour perception was altered.

DOES AN ADVERTISEMENT CONSTITUTE A WARRANTY?

IN the Westminster County Court on Tuesday last, before Judge Lumley Smith, Messrs. Pulvermacher, Limited, electric belt makers, of Regent-street, W., brought an action for four guineas, the balance of the purchase money of an electric belt supplied to Mr. H. Mott of Oxford. Mr. Mott was led to write to Messrs. Pulvermacher by advertisement, and paid one guinea on account of a five-guinea belt described as "doubly concentrated." The belt in no way relieved his symptoms of migraine and irritability but rather, in his opinion, made him worse. So he returned it. Judge Lumley Smith held that the advertisement of their belt issued by Messrs Pulvermacher was a warranty to cure "all the ills that flesh is heir to" As the defendant was not benefited by the belt he found in his favour, but did not give him costs. This is a judgment which may be of considerable importance. Many well-advertised quack remedies promise to heal everything. Can the public recover its money when it discovers as it always does, that the remedies are useless?

DIPHTHERIA IN CAMBRIDGE AND CHESTERTON: THE VALUE OF PREVENTIVE INOCULATIONS.

AN outbreak of diphtheria recently occurred in the above-mentioned districts which have a population of about 50,000. The first case was notified on Oct. 14th and the last up to the present time, on Nov. 15th, and in all there were 60 cases notified during the five weeks. Up to and including Oct. 24th there were 12 cases notified, out of which number four ended fatally. Nine of the cases occurred in children attending a higher grade school, two were members of the family of a scholar and one was a nurse in the hospital. The school was closed and on Oct. 24th Dr. B. Anningson, the medical officer of health, asked for the assistance of the Pathological School of the University. Professor Sims Woodhead was accordingly appointed consulting bacteriologist and Dr. L. F. Cobbett undertook the work of bacteriological examination and the duty of providing prophylactic injections of antitoxin where no medical man was in attendance. The method of procedure was as follows The infants attending the school were visited in their own homes by a staff of willing helpers; a bacteriological examination was made, and a prophylactic injection of antitoxin was offered to all these. This was accepted in the majority of cases. An offer of antitoxin and bacteriological examination was put at the disposal of all medical practitioners for their poorer patients, and this was notified to them in a circular by the medical officer of health. Four cases, the first of which could be directly traced to the above mentioned school, having occurred in three other schools these were closed, and the children attending them and their young brothers and sisters were examined bacteriologically and offered a preventive injection. Circulars were sent to the superintendents of the Sunday-schools throughout the town, recommending the closure of their schools. A home was opened for those children in whose mouths suspicious bacilli had been found but who had shown no symptoms of the disease. To this home about 30 children who could not be satisfactorily isolated in their own homes were sent. Circulars were sent to parents whose children had suffered from diphtheria, pointing out how to aid in dealing with disinfection under the supervision of the medical officer of health. A letter inclosing the circular just mentioned was sent to the medical practitioners asking them to keep their patients and suspects under supervision until three consecutive bacteriological examinations giving negative results had been carried out Immediately following the preventive use of antitoxin and the commencement of bacteriological examinations there was an increase in the daily number of notifications largely caused, no doubt, by the recognition of mild cases which might otherwise have escaped notification The largest number of daily notifications (nine) was reached on Oct 30th, after which date they fell rapidly, 10 cases only having been notified in November The value of the preventive injections has been shown by the fact that only one slight case of diphtheria has occurred among those treated, many of whom were found to be harbouring the diphtheria bacillus at the time, while among the elder members of their families who had not been injected several cases occurred No complaints of rashes or of other complications have been heard from the parents of the children who were injected

THE CORONER AND THE DEATHS OF LUNATICS IN POOR-LAW INSTITUTIONS

THE Local Government Board have issued an Order directing that within 48 hours after the death of a lunatic in any Poor law institution notice of such death shall be sent by the superintending officer of the institution to the coroner of the district in which the institution is situated The notice is to be accompanied by a statement signed by the medical officer, or the medical superintendent, or the medical man who attended the lunatic in his last illness, and containing certain prescribed particulars The Order will come into operation from and after Dec 1st, and it is in our opinion an excellent innovation as tending to reassure the public in a very real and practical manner that everything that is possible is being done for a sadly afflicted class We print it in full on p 1528 of this issue, and congratulate the Coroners' Society upon the success of their efforts A thousand lurid but unsupported tales, with an occasional case or two, like the terrible one of recent occurrence at Crumpsall, have bred in the public mind suspicion that the cause of death of lunatics in Poor law institutions would not always bear scrutiny The full publicity of a coroner's inquest will remove this suspicion

THE SEXUAL LIFE AND THE OFFSPRING OF EPILEPTICS

Dr Bourneville and Dr Poulard have published in the *Progrès Médical* of Sept 29th the concluding part of a series of three articles dealing with the sexual life, marriage, and descendants of an epileptic, which presents in an interesting way an epitome of the question of hereditary transmission The case which embodies the facts is that of a young man who began to have epileptic seizures in his thirtieth year He was possessed of great sexual vigour and he married and begat several children The epilepsy was of the idiopathic type and ran its usual course At present the patient is intellectually weak and suffers from loss of memory and diminished sexual power He begat eight children, two of whom died from athrepsia while a third died from intestinal catarrh (cholera infantum) A fourth child is alive and is the subject of convulsive attacks with twitchings of the eyes (*petit mal*) and violent outbreaks of temper Another child has epileptic seizures (*haut mal*) and suffers from hallucinations of sight and disturbances of sleep A sixth child is very nervous and has night-terrors Thus of eight children six are the subject of grave neurotic troubles inherited from an epileptic father Dr Bourneville and Dr Poulard discuss at some length the question of the marriage of epileptics and conclude that the marriages of those who are the subjects of epilepsy *petit mal* and *haut mal*) and epileptoid psychoses and neuroses (epileptic imbecility, epileptic insanity, and hystero epilepsy) should be forbidden or strongly discouraged

THE ASSOCIATION OF PORT SANITARY AUTHORITIES

A MEETING of the Association of Port Sanitary Authorities will take place to-day (Friday) in the Guildhall at 10 30 A M The special business before the meeting will be to consider the recent reply to the association from the Local Government Board relating to the resolution passed at the last annual meeting *re* the notification of the existence of infectious diseases at foreign ports Three discussions that promise to be interesting are announced Mr G J. Woodman will open a discussion on the "Exemption of Government Vessels from the Provisions of the Public Health Act with Regard to Infectious Diseases" Mr Councillor T Clarke (Liverpool) will open a discussion on "The Precautionary Measures Adopted in Regard to Plague," when delegates will be invited to narrate briefly the measures adopted at their respective ports Mr Alderman T Walton (Southampton) will open a discussion on "Port Sanitary Administration as it Exists, and the Further Powers Required"

FUNCTION OF THE PROSTATE GLAND

IN the October number of the *Bulletin of the Johns Hopkins Hospital* Dr George Walker of Baltimore describes a number of experiments which have led him to the conclusion that the function of the prostate gland is to furnish a fluid in which the spermatozoa can move freely He found that there was no movement of the spermatozoa in semen from the testicle itself or from the globus major Semen from the globus minor and vas *deferens* showed slight movement where the fluid was thin, but there was no movement in the portions of thick consistence which formed the bulk of the sample. On the other hand, in a mixture of prostatic juice and semen from the substance of the testicle there was *distinct* but *not lively motion*, while *semen out of the* epididymis with prostatic juice showed lively motion which continued unabated for some hours Semen from the epididymis with normal salt solution also gave lively movement in the places where a mixture had occurred In other areas where the liquid was thick no motility was apparent For the continued motility more is necessary than the mere thinning, for in the salt solution all movement ceases after three hours, whereas in the prostatic juice it continues for over 20 hours

CONVICTION OF AN ABORTIONIST.

ON Nov. 20th Ernestine Katz, a midwife, was tried at the Central Criminal Court, before Mr Justice Darling, on a charge of having murdered a young woman named Kate Kennedy The prisoner, a German, resided in Whitechapel, and it was alleged that on June 30th she performed an illegal operation upon the deceased by means of "an instrument" The case for the prosecution was that the deceased woman's death was occasioned by the operation which the prisoner was alleged to have performed upon her Much legal interest was attached to the manner in which the depositions had been taken and a long argument ensued, but the main question for the jury was as to whether the prisoner was guilty of murder or of manslaughter, the facts of the case being perfectly simple. Mr Arthur Hutton for the defence *denied* that *the prisoner had performed* an illegal operation, and he urged that what she did was for a perfectly lawful object If, however, the jury did not take that view, he argued that they ought to find only a verdict of manslaughter Mr Justice

Darling directed the jury upon the law applicable to the case, and a verdict of "Manslaughter" was returned. It then appeared that when the prisoner was arrested a number of documents were found upon her which showed that in 1897, at Berlin, she was charged with an offence of this very same nature, and that she absconded from her bail to this country. Mr. Justice Darling is reported as saying that the jury had found the prisoner not guilty of murder but guilty of manslaughter, having been informed that that verdict was hardly possible if they were of opinion that she, in doing what they found that she had done, did not know that she was performing an act which was likely to have fatal results. In their opinion, apparently, the prisoner was an extraordinarily ignorant person in the practice of the business which she carried on. The judge plainly intimated that he did not share the opinion of the jury, and we entirely endorse his view. It would seem impossible that the prisoner did not know that she was performing an illegal, and possibly a dangerous, act. If a person knowingly inflicts an injury upon another a felonious act has been committed, and the assailant is liable for any result which may occur; if death ensues he or she can be tried for murder. In the case of Ernestine Katz we consider that "Murder" ought to have been the verdict of the jury, and that the sentence of ten years' penal servitude passed upon the prisoner cannot be considered a severe one.

THE DANGERS OF ELECTRIC LIGHTING.

THE notion was at one time current that an electric installation secured the householder from many of the risks attendant upon a gas installation or the use of oil and candles. It is very doubtful if this is so, at any rate under the present methods of laying cables and of "wiring" our houses. Recent events which have come to our knowledge call very seriously for a fresh inquiry as to the methods adopted for supplying electricity to our houses. It is common knowledge now that an otherwise innocent current—that is, one of low voltage—may through certain defects become an exceedingly dangerous current of enormous voltage. "Earthing" is, of course, the main source of trouble and the generally offered excuse, but if electric lighting is to be our mode of obtaining artificial light "earthing" must be overcome and it seems to us that "earthing" has not been overcome—it is happening on all sides and in several instances with most alarming results. Leakage has led to outbreaks of what have proved to be serious fires. Last week, for example, a serious outbreak of fire took place at some photographic studios in Regent street and the fire brigade attributed the cause to the fusing of the cables at the switchboard. It is even said that the electric [illegible] used in these studios for the purpose [illegible] majority of cases [illegible]

a very high and dangerous current may be tapped by telephone wires, gas-pipes, or ordinary voltage electric cables. No wonder, then, that public electricity is becoming a serious cause of outbreaks of fire. Just upon a year ago we reported an instance in which a drawing-room floor was ignited either by the overheating of wires or by the production of sparks through a defective system of insulation. The system of wiring must sooner or later be reformed, and the sooner the better, or otherwise disasters are certain to arise. The subject was ventilated in the press, including our own columns, some months ago, and on the face of it there was then some promise that something definite would be [illegible] As a matter of fact nothing or very little has been done, [illegible] all those who use the electric light are still at the [illegible] of defective fittings and under the risks of tapping a powerful and dangerous current intended only perhaps for arc installation on a large scale. These possibilities are [illegible] alarming and the Board of Trade should be [illegible] with a view to enforcing by very definite [illegible] safer method of installation of domestic electric [illegible] than appears to be in vogue now. Until this [illegible] we may only too surely expect a crop of [illegible] and no confidence, it seems to us, can be placed [illegible] electric installation until cables and wires are [illegible] separate tubes and "return" wires are provided. [illegible] of doing something in this direction is all [illegible] emphasised by the fact that our streets are [illegible] a close network of all sorts and conditions of [illegible] and mains.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION [illegible] GREAT BRITAIN AND IRELAND

THE Medico-Psychological Association of [illegible] and Ireland held a general meeting on Nov. [illegible] Chandos-street, W., which was presided over by Dr. [illegible] Beach and was numerously attended. The [illegible] at four and lasted for nearly three hours, [illegible] with interesting discussions on each, being [illegible] time. The first paper was on Mental Disorders [illegible] on Toxæmias, by Sir Dyce Duckworth, and [illegible] printed in full at p. 1475 of this issue of [illegible] Our report of the discussions and of the other [illegible] appear later. Sir Dyce Duckworth was followed [illegible] F. W. Mott, who spoke at some length on [illegible] Inherited Tendency. After Dr. G. H. Savage [illegible] tributed a spirited criticism Dr. E. Goodall [illegible] Mercier continued the discuss[illegible] man; Travel. [illegible] Use in Mental [illegible]cedure was as follo[illegible] subject [illegible] addre[illegible] school were visited in their ov[illegible] val[illegible] willing helpers; a bacteriologic[illegible] [illegible]de, and a prophylactic injection of anti[illegible] to all these. This was accepted in the [illegible] latitude for a homœopathic practitioner. He said that mortality from blackwater fever under "allopathic medication" was appalling, and that chronic malaria would be extremely rare under homœopathic treatment. Mr. A. L. Jones thereupon promised to get "*a qualified homœopathic medical man*" a post on the West Coast. Mr. Jones is, in our opinion, doing a very imprudent thing in thus countenancing homœopathy. He will probably consider our view to be based upon narrow selfishness whatever we say, but such have been the services of Liverpool to scientific medicine that we cannot let these services be endangered without protest. Homœopathy is based upon theories exactly contradictory to medical knowledge, so that there can never be any common ground upon which a medical man and a homœopath can discuss a medical subject. Now, as medical men cannot work with homœopaths, and as all the men of any scientific position in the country are with the medical men, had not the Liverpool Chamber of Commerce better stick to the side whence it can always obtain a supply of sound assistance? By the way, there is not such a thing as a qualified homœopathic medical man, so that Mr. Jones has not committed himself to anything. A man can qualify in medicine and become a homœopath; but he cannot qualify in homœopathy, for the General Council of Medical Education and Registration does not recognise homœopathy.

PNEUMOCOCCIC OTITIS MEDIA.

OTITIS media is now well recognised as one of the manifold consequences of pneumococcic infection. It may be primary or secondary to pneumonia. At the meeting of the Société Médicale des Hôpitaux of Paris on Oct. 26th Dr. Hirtz related the following interesting case, the first on record in which otitis media was apparently contracted by contact with a patient suffering from pneumonia. A man, aged 65 years, had pneumonia of the right lung, which terminated favourably by crisis on the ninth day. His wife nursed him day and night and emptied and cleansed the spittoon. On the fourth day she had a purulent discharge from both ears. The pus was whitish and grumous and without odour. The discharge lasted about 12 days. She did not suffer in any way and under antiseptic treatment rapidly recovered. Both tympanic membranes were perforated. The appearance of this double otitis without antecedents in a person in contact with a patient suffering from pneumonia caused Dr. Hirtz to suspect that it was due to contagion. In the pus numerous pneumococci and small bacilli, the nature of which was not determined, were found. Contagion may have taken place through the auditory meatus or through the nose, possibly from the patient's hands soiled by contact with the spittoon. According to Zaufal the pneumococcus is the ordinary cause of primary otitis media or of otitis media ascribed to cold, but pyogenic microbes are usually found in secondary otitis. This case shows that those who attend on pneumonic patients should observe the same precautions as in cases of tuberculosis

DANGEROUS LUCIFER MATCHES.

has been a matter of frequent observation during the month or so that many of the wax vestas supplied to public have to a large extent had no ignition tip upon or that if they had the head immediately flew off upon ding, scattering sparks in all directions. In short, for some on which we do not presume to supply, an epidemic of ctive wax matches appears to have set in. We approach subject only from the point of view of its very obvious ggers. We have seen narrow escapes of very serious ry being done by particles of fired phosphorus shooting ously near the eye in this way. In the smoking carriages ailway trains the danger is more obvious perhaps than anywhere else. A passenger strikes one of these matches and the flaming head flies off in the direction of a fellow passenger. In the house the flaming head may bury itself in a carpet or rug and there continue to glow until it ignites the material. We understand from a very responsible person connected with the subduing of outbreaks of fire in the metropolis that "unknown causes" are probably largely due to the lost glowing head of a wax vesta. Cheapness, we fear, is largely responsible for this nasty dangerous match. Matches are made at a tremendous speed, and we doubt if they are ever examined or tested before they are packed in boxes. We have counted as many as 30 per cent. of matches in one box without heads at all, while the majority of those with heads lighted viciously and in the dangerous manner which we have described. It is to be wished that the public would give up using wax vestas altogether or, at all events, those matches which contain yellow phosphorus. The burns from phosphorus are exceedingly painful and difficult to heal, while cases have been known in which death has followed through blood-poisoning set up by a wound caused by a scintillating match-head. Again, in discarding matches made with yellow phosphorus the public would be taking a decisive step towards banishing from our match factories that dreadful disease known as necrosis or "phossy jaw."

THE Queen in Council has granted to the Great Northern Central Hospital Letters Patent under the Great Seal incorporating the hospital by Royal Charter under the title of "the President, Vice-presidents, and Governors of the Great Northern Central Hospital."

DR. THOMAS BUZZARD, a Fellow and member of the Council of King's College, London, has been appointed one of the representatives of the College upon the Senate of the University of London in succession to Lord Lister who has resigned.

THE Executive Committee of the Prince of Wales's Hospital Fund have issued another appeal for subscriptions, the falling off in the financial support which the Fund has received this year being serious.

THE IRISH POOR-LAW MEDICAL SERVICE.

IT is not unusual to hear in the political world such cries as "Another Irish grievance" and "Justice to Ireland" when questions relating specially to the Green Isle are being discussed; but we think that those who are conversant with the working of the Irish Poor law Medical Service will freely admit that it is oppressed with grievances which common justice demands should be redressed. We propose to lay before our readers a few of these grievances, and to suggest some ways by which they may be remedied.

Method of appointment of medical officers in the Irish Poor-law Service.—Up to the date of the passing of the Local Government (Ireland) Act, 1898, the dispensary medical officers were appointed by committees, among whom there were some members (*ex officio*) of position and education. That Act, however, delegated the power of election to the guardians, who are in country districts almost all small farmers and shopkeepers. As a result it is too often a candidate's religion, politics, or local connexions which determine his selection, his professional standing being regarded as of little import. Further, there is no promotion. The dispensary medical officer remains, as a rule, in the original district to which he was first appointed; he has no stimulus to work, his salary does not steadily rise, and he finds there is no chance of advance. With such prospects the able men coming from the medical schools will not enter the service and in the end it will be the poor who will suffer most. To remedy such a state of affairs the Irish Medical Association have recommended the

PROFESSOR CALMETTE ON PREVENTIVE MEASURES AGAINST PLAGUE.

PROFESSOR CALMETTE, Director of the Pasteur Institute at Lille, in delivering the third Harben Lecture at the Examination Hall of the Royal Colleges of Physicians of London and Surgeons of England on Nov. 21st, said it was now impossible to deny that the use of anti-plague serum as a preventive measure was an excellent means of preventing propagation of plague in an infected centre, as by its means persons exposed to the contagion could be rendered absolutely and immediately immune. Unfortunately the immunity thus obtained was of short duration, lasting only from 12 to 15 days, and it was therefore necessary during an epidemic to repeat the injection every second week. This was a serious inconvenience, to which must be added the difficulty of procuring a sufficient quantity of serum to vaccinate and revaccinate a large number of individuals. It had been proved by experiment on small animals that after repeated injections under the skin or into the veins of cultures of plague bacilli killed by an hour's exposure to a heat of 65° or 70° C., it was possible to inject after a sufficient interval into these same animals without ill-effects virulent cultures which would otherwise have been fatal in from three to five days. Haffkine, in India, having observed that these cultures vaccinated more effectually because they were richer in microbic bodies killed by the heat, added butter or cocoanut oil to his bouillons. These fatty substances floating on the surface enabled the plague bacilli to develop and form stalactites. A slight shake to the vessel containing the culture caused the fall of these stalactites; they were not long in re-forming, and thus in three or four weeks a liquid rich in microbic elements could be obtained. Haffkine then warmed these cultures, added a small quantity of phenic acid as a preservative, and injected them in average doses of from two to three cubic centimetres. If the injection of dead cultures was carefully repeated even twice or three times after seven or eight days' interval a more durable immunity could be obtained which would extend to three or four months in a monkey or guinea-pig and six months in a rat. It was therefore possible that, as Haffkine believed, a single inoculation with cultures killed by exposure to heat would suffice in many cases to render a man sufficiently immune to pass through a plague epidemic. This method was, however, open to some objections. Leumann had already called attention to the different degrees of virulence in the cultures employed and the variability in the composition of the mediums used for the preparation of the vaccine, thereby rendering them very uncertain. Further, he had proved with Salimbeni that during the period of immunisation with the heated cultures animals were extremely susceptible even to minute doses of plague virus. It followed, therefore, that if anyone during the incubating period of a slight attack of plague were to undergo the Haffkine inoculation the attack would be greatly aggravated—it would probably be fatal. But despite all this, it was incontestable that vaccination by heated cultures was capable of rendering very great service in times of epidemic. Many efforts had been made towards greater efficacy and practicability. In Italy, Terni and Baudi proposed to prepare anti-plague vaccine from the peritoneal secretions of rabbits inoculated with the plague bacilli in the peritoneum. This secretion, laden with leucocytic elements, was diluted in chemical solutions of sea-salts, placed for a few hours in a stove and heated to 60° C. In this way a liquid possessed of a fair amount of toxicity was obtained which, administered in weak doses, produced in animals a vaccinal immunity more lasting, according to its discoverers, than a single inoculation of the Haffkinian cultures. Yersin proposed to vaccinate with a species of slightly virulent plague bacilli by inoculating living microbes by means of the lancet. He (Professor Calmette) had studied the question in his laboratory during the past year. To prepare his vaccine cultures he employed a plain virus which originated in Oporto and which had never passed through any kind of animal; he kept it up by culture on gelose, re-fertilising every eight or 10 days, the culture being raised each time to a temperature of 36° C. for 24 hours. The cultures were placed, still on gelose, in large flat bottles in which there was produced after 48 hours an enormous microbic development. 20 cubic centimetres of sterilised water were then put into the flat bottle, the cultures were scraped with a thin glass rod, and the emulsion thus obtained was poured into a filter upon fine sterilised linen to retain the fragments of gelose. The liquid containing the microbes was poured on to a paper filter and the microbes left on the paper were washed in sterilised water. They were then placed in a small quantity of water, heated for an hour up to 70° C., and afterwards dried in a vacuum. Thus bodies of dried plague bacilli free from every trace of toxin were obtained. These were kept in sealed tubes until required. For use they were suspended in sterilised salt water and injected under the skin or into the veins. Now that the comparative value as preventives of the anti-plague serum and of vaccine injections prepared by bacilli killed by heat had been considered prophylactic rules could be laid down. This prophylaxis must be based entirely on the knowledge recently acquired concerning the way in which the disease was propagated. The researches of Simond, Yersin, and Hankin had demonstrated that the malady was spread chiefly by fleas and rats. It was, therefore, necessary to seek the best methods of destroying the largest possible number of parasitical insects and rats wherever there was an outbreak of plague. The best way for a town to avoid plague epidemics was to exterminate as completely as possible the rats and mice which populate houses, shops, and sewers; and it was desirable on the first appearance of a case of plague that a confidential note should be distributed to medical practitioners detailing the principal symptoms of the bubonic and pneumonic forms of plague, with the precautions to be taken to avoid contagion, and giving every necessary information respecting diagnosis and preventive vaccination.

Obituary.

DENNIS EMBLETON, M.D. DURH., M.D. PISA, F.R.C.S. ENG. F.R.C.P. LOND., L.S.A.

EARLY on the morning of Monday, Nov. 12th, there died at his residence, Newcastle-upon-Tyne, Dennis Embleton, the "grand old man" of the medical profession in the north of England. He was born at Newcastle-upon-Tyne on Oct. 1st, 1810, and consequently had completed his ninetieth year. He commenced the study of medicine in the year 1827 by apprenticeship to Mr. T. Leighton, at that time senior surgeon at the infirmary, to whom he paid, as was usual in those days, a fee of £500. He also studied at Guy's and St. Thomas's Hospitals and at Grainger's and, we believe, at Pilcher's Schools of Anatomy in London. In June, 1834, he became a Member of the Royal College of Surgeons of England. In the following year he was admitted a Licentiate of the Society of Apothecaries of London. In 1843 the Royal College of Surgeons of England instituted its Fellowship and on Dec. 7th of that year Embleton was one of the distinguished members of the profession upon whom the honour was conferred. Of the other original Fellows only two, Carsten Holthouse and Henry Spencer Smith, now remain amongst us. In 1836 the University of Pisa admitted him after the usual examination to the degree of Doctor of Medicine. Ten years afterwards he became a Licentiate of the Royal College of Physicians of London *intra urbem*, as it is marked in his own note. In 1853 the University of Durham admitted him to its M.D. degree by diploma and in 1859 he became a Fellow of the Royal College of Physicians of London. Between the years 1834 and 1837, when he finally settled in practice as a physician in his native town, Dr. Embleton spent a great part of his time in the South of Europe, studying in Paris, Rome, Bologna, Pisa, and other places. He was a great pedestrian then and he wandered on foot over France, Spain, and Italy. He was never tired of talking of the adventures of those days—those halcyon days—of the beauties of the southern scenery, of the grandeur of the cities, and of the manners and habits of the people with whom his own kind and genial disposition rendered it easy for him to amalgamate. He spoke French and Italian well, and was familiar with the literature of France and of Italy and loved the warmth and brightness of their sunny

climate as much as if he had been a native To the end of his life he retained his affection for Frenchmen and Italians, who were always welcome to his hospitable board and to his almost open house In the year 1834 a school of medicine was established in Newcastle by Dr George Fife, Dr Knott, and Mr Frazer—Mr John Fife (afterwards Sir John) Mr Potter, and Mr McAllum joining later Five years after its establishment Dr Embleton joined as lecturer on anatomy and as registrar His connexion with the College was a long one, extending over a period of 33 years In 1838 he was lecturing on anatomy and physiology In 1852 he was appointed reader in medicine at the Durham University, and in 1870 he became, on the closer connexion of the medical school at Newcastle with the University of Durham, the first professor of medicine and of the practice of physic This office, however, he only held for a very short time, Dr Edward Charlton succeeding him in 1872 when Dr Embleton's connexion with the Newcastle Medical School and with the University of Durham ceased From 1858 to 1872 Dr Embleton was the representative of Durham University on the General Medical Council He was physician to the Newcastle-upon Tyne Infirmary from April 1853 to May, 1878, when he became consulting physician which position he occupied at his death From 1856 to 1873 he was physician to the Newcastle upon Tyne Dispensary and Fever House During the active portion of his long professional career Dr Embleton contributed a very large number of papers to current medical literature One on Tenderness and Pain of the Pneumogastric Nerves and the Importance of the Sign in Cases of Disease of the Stomach, Liver, and Heart attracted the attention of the late Sir Thomas Watson, who alluded to its importance in his classic lectures on the Practice of Physic—lectures which it is as great a delight to read to day as when they were written It was not, however, with medicine only that Dr Embleton was identified He took an active interest in science generally and in literature He was a good antiquarian and a first rate naturalist At different times he was vice president of the literary and philosophical, the natural history, and the antiquarian societies of Newcastle He was for years one of the best known educational leaders in the north of England, no *savant* ever visiting Newcastle without asking for, and making the acquaintance of, Dr Embleton He wrote papers on local folk lore, dialogues and poetry in Northumbrian vernacular, short histories of the Newcastle Medical School and of Featherstone Castle lives of his friends Joshua Alder, John and Albany Hancock, and W C Hewitson His contributions on natural history, of which he was particularly fond, were numerous The late Prince Consort at the request of the Queen, sent him a book on the natural history of Braemar in acknowledgment of a work published jointly by himself and Albany Hancock on the Anatomy of Doris He was an authority on the nudibranchiate molluscs and on eggs, birds, fishes and local fossils, writing many valuable and interesting papers, sometimes by himself, at others in connexion with Joshua Alder or Albany Hancock Dr Embleton married in 1847 Miss Turner, a lady herself devoted to natural history and scientific pursuits but he became a widower in 1869 He has left two daughters, one of whom—the elder—is married The other daughter who is unmarried, lived with her father and devoted her life to his comfort and welfare, nursing him through a long and trying illness with a care and affection which could not have been exceeded His only son Dr Dennis Cawood Embleton died at the early age of 46 years only a few months ago at Bournemouth, where for a number of years he had conducted a large practice and where he was much respected and beloved A grandson, Dennis Embleton, is an undergraduate studying medicine at Christ's College, Cambridge

Dr Embleton had outlived his generation and probably, with the exception of Lord Armstrong and Mr T Lightfoot (the oldest surgeon in Newcastle), none of his old friends or contemporaries remain The funeral took place on Thursday, Nov 15th, at St Andrews cemetery The coffin was covered with beautiful wreaths of flowers many of which had been sent from long distances and from various parts of England Sir George Hare Philipson and the members of the Durham University College of Medicine attended, and among the mourners, besides relatives were representatives of the institutions with which Dr Embleton had been connected and many well known citizens of Newcastle

RICHARD BENJAMIN ANDERSON, F R C S ENG

WE announced briefly last week the death of Mr R B Anderson, late of Tobago, whose name is well known in the medical profession first as the victim of a terrible miscarriage of justice, and second as a would be reformer of the most drastic sort in medical politics and honorary secretary of the Corporate and Medical Reform Association

Mr Anderson, who was 53 years of age at his death, was born in Lincolnshire, being the son of a medical man He received his medical education at St Mary's Hospital, and in 1869 became a Member of the Royal College of Surgeons of England He obtained several prizes and held appointments as house surgeon both in London and Plymouth In 1873 he became a Fellow of the College, and then joined his brother, Mr James G Anderson, in the West Indies, settling in Tobago, where he attained considerable success in practice and received the appointment of Colonial Surgeon This office, which, after he had held it for five years was discontinued, brought him a small pension by way of compensation By the year 1889 he had been 16 years in practice in the island, and was then a justice of the peace, a member of the legislative body, and a landowner. In that year he was consulted by a coloured woman named Marshall who suffered from a necrosis of the lower jaw, and Mr Anderson with the assistance of a medical friend cut down upon the sequestrum The sequestrum did not separate immediately and the patient and her friends, not understanding the pathology of the condition, were much disappointed at the delay in the cure, and finally became so objectionable in their manner that Mr Anderson refused to continue to treat the case. A fortnight later the sequestrum became loosened and was easily removed by another medical man with his finger Mr. Anderson's professional charges not being paid, he took proceedings in the Petty Debt Court, and after some inexplicable delay found that the Chief Justice, Sir John Gorrie, who was then in the island of Trinidad, had given special directions that this case was not to be tried until his (Sir John Gorrie's) arrival in Tobago In the meantime Mrs Marshall and her husband sued Mr Anderson *in forma pauperis* for £15 damages There was no shadow of proof that the female plaintiff had sustained any injury, and the principal charge alleged against the defendant was neglect, inasmuch as he had improperly ceased to attend the plaintiff and had retired from the case before recovery was complete In the result the Chief Justice, in the beginning of 1890, gave judgment for the plaintiff for the sum of £17 10s, with costs for breach of contract—for which the plaintiffs had not sued, neither had their plaint been amended to include it Sir John Gorrie further stated, without any reservation, that a medical man, as such, and merely by becoming qualified, was bound to attend all cases of illness to which he was summoned, and that no medical man had a right, without the consent of the patient, to abandon any case which he had begun to treat, even where other medical aid was available and where the patient was running no risk from such abandonment, and that by so doing he laid himself open to an action at law, civil or criminal He also stigmatised the making of contracts prior to attendance as an unprofessional and improper act on the part of the practitioner It is almost needless to add that Mr Anderson's claim for fees was disallowed by Sir John Gorrie About a year afterwards—viz, on Jan 20th, 1891—summonses were taken out against Mr Anderson by the Marshalls The plaintiffs sued *in forma pauperis*, no affidavit was made to shew that the claims were unpaid The total amount of the judgment debts, including costs, was £42 2s The case was tried in Tobago before Mr Justice Cook and Mr Anderson was on Jan 23rd ordered by this judge, upon adjournment of his examination to give his security in £500 and also to find bail in £500 for his appearance at the adjourned hearing of the summons, and in default of giving such security he was committed to prison where he remained until the adjourned hearing was resumed on Jan 30th On that day Mr Justice Cook again adjourned the hearing after some examination and required Mr Anderson to find security for his appearance, as before in two sums of £500 each Five well known residents three of whom were members of the Legislative Council perceiving that a grave injustice was being perpetrated, went in a body to the judge to offer the security Mr Anderson was then liberated, having been imprisoned for not finding £1000 bail as security for a debt of £42 2*s.* which had never been legally proved against him.

That the administration of justice in the West Indies by Gorrie and Cook was a disgraceful farce had long been the opinion of the European residents. Mr. Anderson, who had petitioned the Crown and been threatened with proceedings for contempt of court consequently, was sent to England in 1891 by public subscriptions raised in Trinidad, to lay his wrongs before the home authorities and the public. On Sept. 14th of that year he instituted his remarkable action in the Court of Queen's Bench against the Trinidad judges (Anderson *v.* Gorrie and others). The facts disclosed were too flagrant to be overlooked. In 1892 a Royal Commission, consisting of Sir William Markby and Sir Frederick Pollock, was appointed to inquire into the administration of justice in Trinidad and Tobago, and their report resulted in the removal of Mr. Justice Cook from office. Sir John Gorrie was also interdicted pending the formal bringing of charges against him, but the interdiction was soon followed by his death. Mr. Anderson's action against the judges only came on in April, 1894, and occupied seven days, before the late Lord Chief Justice Coleridge and a special jury of Middlesex. He appeared in person and successfully held his own against five counsel employed by the defendants. In the course of the trial Lord Coleridge stigmatised the imposition of the bail already mentioned as "a piece of unmitigated, unlawful tyranny," and in the course of his summing-up said:—"The proceedings for contempt of court against the plaintiff for having petitioned the Queen were quite unjustifiable. Then judgments having been obtained against Mr. Anderson for £42, Mr. Justice Cook held him to bail for £500. He confessed he could not understand how an English judge could have so acted." The verdict was as follows:—"The jury find that the defendant Cook oppressively and with malice overstrained his judicial powers to the prejudice of the plaintiff, and the wilful perversion of justice, and found a verdict for the plaintiff for £500." Lord Coleridge, however, entered judgment for the defendant on the ground that no action could lie against a judge for an act done in his judicial capacity, and this judgment was confirmed by the then Master of the Rolls (Lord Esher) and the Court of Appeal.
